Manuscript Type:	Research Paper
Keywords:	cooperative learning, experimental study, quantitative research, physics education, classroom
Keywords (user):	jigsaw classroom, intrinsic motivation, basic needs

Abstract

Twelfth grade physics classes with 344 students participated in a quasi-experimental study comparing two small-group learning settings. In the jigsaw classroom, in contrast to the cyclical rotation method, teaching expectancy as well as resource interdependence is established. The study is based on the self-determination theory of motivation which states that the satisfaction of the 'basic needs' for experiencing autonomy, competence, and social relatedness is essential to promote intrinsic motivation. Regarding the experience of competence, a small effect in favour of the jigsaw classroom was found, whereas students in the cyclical rotation setting showed medium-sized benefits in experiencing autonomy. A path analysis revealed that these opposing effects balanced each other, that is, no effect from small-group method to intrinsic motivation was found.

In contrary to the motivational variables, achievement effects depended on the underlying study topic: based on scanning electron microscopy, the cyclical rotation setting outperformed jigsaw classroom, whereas an opposed trend is observed with regard to the microwave oven learning unit. The higher interestingness of the latter learning unit was revealed as a weak mediator from study topic to academic achievement.

Introduction

Research on the effects of cooperative learning indicates that the learning process and the subsequent outcomes are strongly fostered by cooperative learning methods (Slavin , Hurley & Chamberlain, 2003). As shown in the meta-analysis conducted by Springer, Stanne & Donovan (1999) cooperative methods can be established with success in science, mathematics, and technology. Almost all of the studies included in this meta-analysis compared various forms of cooperative learning to more traditional methods. Relative little research has investigated in comparing two (ore more) small-group learning procedures. Research in this field should gain insight into various strengths as well as weaknesses of the different forms of small-group learning settings. In this paper we focus on the comparison of two forms of small-group learning: the jigsaw classroom and the cyclical rotation method. The jigsaw learning technique was first developed and implemented by Elliot Aronson (1978 & 2002) in the 1970's. In the jigsaw classroom, the lesson is divided into segments. Students meet first with other students who have been assigned the same segment in an 'expert group'. Together, they research their segment, discuss, and clear up questions. The students then leave their groups to join 'jigsaw groups'. Each student in each group teaches the whole group about his or her expert subtopic, **thus covering the whole topic**. By contrast, in the cyclical rotation method the groups' composition is not varied while 'rotating' from subtopic to subtopic. Both methods differ mainly with respect to two aspects. First, in contrast to the cyclical rotation groups, the learners in the expert groups are aware of the demand

1
2
3
4
5
6 to teach their peers in the jigsaw group ('teaching expectancy', Renkl, 1995) and
7
8 they subsequently teach each other. Second, due to the task-specialisation in the
9
10 jigsaw setting, each group member is accountable for a unique part of the activity
11
12 and the students in the jigsaw groups are dependent on their experts' knowledge.
13
14 In contrast, the cyclical rotation groups have access to the whole material and
15
16 work together without separate responsibilities. Thus, 'resource interdependence'
17
18 is established in the jigsaw condition (Slavin, Hurley & Chamberlain, 2003).
19
20 Most researchers in cooperative learning agree that individual accountability as
21
22 well as positive interdependence are essential for fruitful cooperative working
23
24 (Antil, Jenkins & Wayne, 1998). The most striking differences between both
25
26 methods are resumed in Table 1.

30
31
32
33

34 [Insert Table 1 about here]
35
36
37
38

39 We focus on the question if these characteristic differences lead to different
40
41 outcomes with respect to academic performance and intrinsic motivation. It is
42
43 widely believed that the jigsaw method supports intrinsic motivation (Hidi, Weiss,
44
45 Berndorff, & Nolan, 1998). But it is not clear why, and the question arises, if
46
47 other forms of small-group learning like the cyclical rotation method lead to the
48
49 same motivational benefits. In order to shed some light on this issue we refer to
50
51 the self-determination theory by Deci and Ryan (2000).

Framework

Self-determination theory

The self-determination theory postulates that innate basic psychological needs play an essential role for the development and maintenance of intrinsic motivation. The authors identified three needs for competence, autonomy, and social relatedness. They emphasize that intrinsic motivation requires satisfaction of perceived competence as well as autonomy. Following Deci and Ryan all three needs are necessary for intrinsic motivation, albeit the relatedness plays a role primarily in the maintenance of intrinsic motivation. The asserted impact of the relatedness for intrinsic motivation is controverted by Vallerand (2000). He points out that the perception of relatedness has a low relationship with self-determined motivation due to the individualistic type of classroom activities.

A frequently espoused position is that autonomy and social relatedness are incompatible or competing aspects of experience. In contrast, Deci and Ryan strongly emphasize that the need for autonomy refers to the desire to self-organize experience and behaviour and should not be interpreted as detachment or independence. That is, there is no incompatibility with relatedness.

Furthermore in the self-determination theory extrinsic motivation is no static concept, but supports for relatedness, autonomy, and competence allow the person to transform extrinsic motivation into a more self-determined motivation (Ryan & Deci, 2000). The authors identified factors which foster an increasing identification with an object, e.g. its meaningfulness. With respect to the genesis

1
2
3
4
5
6 of interest, the basic needs are important because they provide emotional feedback
7
8 and thus contribute to the development of preferences (Krapp, 2002).
9

10 11 12 13 *Cooperative Learning and Jigsaw*

14
15 From a theoretical point of view there is no unifying approach that could
16
17 explain all the outcomes of cooperative learning consistently (Slavin et al., 2003).
18
19 Nevertheless all theoretical perspectives expect benefits of cooperative learning
20
21 with respect to academic achievement compared to more traditional whole-class
22
23 teaching methods, e.g. frontal teaching. An impressive research effort across a
24
25 range of curriculum areas (in mathematics, science, and technology documented
26
27 by a meta-analysis conducted by Springer et al. (1999)) supports this assertion,
28
29 albeit not all studies agree.
30
31

32
33 Placing students in small groups and telling them to work together will not
34
35 necessarily promote cooperation. The potential of learning together is maximized
36
37 when students realize that they can not succeed unless they facilitate each other's
38
39 learning (Gillies, 2003). Thus, unwanted side effects as 'free-riding' (a group
40
41 member leaves it to the others to complete the task) and 'sucking' (a more active
42
43 student lowers his effort because of the feeling that others are free-riding) should
44
45 be suppressed. The question arises which conditions are crucial for positive
46
47 outcomes of learning in small groups. Although this matter is still under active
48
49 debate (Huber, 2003), there is consensus among most of the researchers, that two
50
51 conditions are indispensable: positive interdependence and individual
52
53 accountability (Antil et al., 1998).
54
55
56
57
58
59
60

1
2
3
4
5
6 In the jigsaw classroom, positive interdependence is established through task
7
8 specialization: the peers depend on the experts knowledge to be successful
9
10 (resource interdependence). In contrast, all members of a cyclical rotation learning
11
12 group work together without separate tasks. The positive impact of resource
13
14 interdependence on achievement is not evident from the research literature (Slavin
15
16 et al., 2003; Buchs, Butera & Mugny, (2004)). In their study Buchs et al. found
17
18 that resource interdependence outperformed working on identical material only if
19
20 the difficulty of the information matches well to the students' level of
21
22 competence. Otherwise peer teaching might be detrimental for the learning
23
24 process due to reduced quality of explanations, which does not allow the listener
25
26 to understand and master the information.
27
28
29
30

31
32 One of the main purposes of cooperative learning is individual mastery of the
33
34 learning material. This is fostered by an individual accountability which exists
35
36 when the individual performance of students is assessed. This prevents the group
37
38 from doing the whole work by one or two students.
39
40

41
42 In the jigsaw classroom the students realize that they have to teach their peers,
43
44 that is, they are responsible for their groups success. From a motivational point of
45
46 view this teaching expectancy might facilitate intrinsic motivation, based on the
47
48 need to have a meaningful impact on one's own environment (Benware & Deci,
49
50 1984). On the other hand, teaching expectancy might lead to anxiety, thus
51
52 deteriorating motivation and performance.
53
54

55
56 Regarding the impact of teaching expectancy on the experts cognitive structure,
57
58 he or she is probably less likely to skip impasses in understanding and thus
59
60

1
2
3
4
5
6 assigning more time to elaborate the material in the expert group. Additionally,
7
8 explaining to someone else is expected to be one of the most effective means of
9
10 elaboration (Slavin et al., 2003). Hence, from teaching expectancy and later
11
12 teaching one would assume positive impact on achievement. According to this,
13
14 Benware & Deci found a stronger cognitive involvement under teaching
15
16 expectancy. Nevertheless, Renkl (1995) reports no positive effect of the teaching
17
18 expectancy on performance.
19
20

21
22 Simons (1997) highlights that autonomy for decision making is crucial for active
23
24 learning. In comparison to frontal teaching the jigsaw classroom as well as
25
26 cyclical rotation learning are characterized by more room to control the own
27
28 learning process, that is, e.g. to adapt the learning speed to the task and to take
29
30 task-related support. Nevertheless there are differences with respect to autonomy:
31
32 the cyclical rotation method allows the scope to access the whole learning
33
34 material whereas the students in a jigsaw group depend on the other experts.
35
36 Regarding the structure of the two methods, in the jigsaw classroom there are
37
38 certain inherent demands, e.g. the composition of new groups and the clearly
39
40 defined division into two separate phases (expert and jigsaw groups). This might
41
42 lead to a detrimental experience of autonomy.
43
44
45
46
47
48
49

50 **The lessons**

51
52 The study is based on two learning units, which were selected by the
53
54 following criteria: the topics had to be meaningful, that is, important for the 12th
55
56 grade level, as well as interesting. Furthermore it had to be possible to divide the
57
58
59
60

1
2
3
4
5
6 material into independent segments, and the degree of difficulty had to be adapted
7
8 to the students capabilities.

9
10 Following Häussler (1987), boys as well as girls of all ages from 11 to 16 have a
11
12 higher than average interest in the context 'Physics as a vehicle to understand
13
14 technical objects in everyday life' and the topic 'Structure of matter'. Thus,
15
16 gaining insight into the microworld by suitable apparatuses seems to be a
17
18 favourable topic for a multitude of students. From these interests it was suggested
19
20 to take the topics 'Physics of the microwave oven' and 'Principles of the scanning
21
22 electron microscope' as learning units. These topics are particular favourable for
23
24 teaching physics in the 12th grade level, since the underlying physical principles
25
26 cover two main areas of the curriculum: the generation and propagation of
27
28 electromagnetic waves as well as the motion of charged particles in electric and
29
30 magnetic fields. For gaining a useful insight into these topics, we give a concise
31
32 survey of both.
33
34
35
36
37
38
39
40

41 *Principles of the Scanning Electron Microscope*

42
43 Free electrons are accelerated by a high voltage towards the sample. When
44
45 the electron beam hits the sample further electrons are released from its surface.
46
47 The so called Everhart-Thornley detector collects these secondary electrons. The
48
49 brightness of the corresponding pixel on the computer screen is controlled by the
50
51 number of electrons collected by the detector per second. To capture the whole
52
53 sample the electron beam is scanned by the magnetic field of current-carrying
54
55 coils. The learning unit consists of these basic information about the components
56
57
58
59
60

1
2
3
4
5
6 of the microscope and its scanning principle. Further the release of secondary
7
8 electrons due to the interaction of the electron beam with the sample is discussed.
9

10 In the group work the following four subtopics are discussed:
11

- 12 • The generation of the electron beam by acceleration of free electrons in the
13 electron gun.
14
- 15 • The force on the electron beam due to the magnetic field of the coils, that is
16 the Lorentz-force.
17
- 18 • The question, how the penetration depth into the sample depends on the
19 energy of the electron beam and the atomic number of the sample material.
20
- 21 • The working principle of the Everhart-Thornley detector.
22
23
24
25
26
27
28

29
30 Additionally, in higher performing classes the physics of the electron lense might
31 be incorporated as a further subtopic. The electron microscope can be used to
32 teach some important advanced physics: the electron beam generates x-rays when
33 penetrating the sample. In order to highlight specific elements in the picture the
34 characteristic lines from the spectrum are captured by an x-ray detector. With
35 respect to quantum physics, the resolution of the electron microscope is ultimately
36 limited by the de Broglie wavelength of the incident electrons. Since these topics
37 are not covered by the current 12th class curriculum in Germany they were not
38 included into the learning unit.
39

Physics of the microwave oven

Microwaves can heat matter only if its molecules have a permanent electric dipole moment. Due to the interaction of the electric field of the electromagnetic wave with the dipole moment of the water molecule, rotational motion is excited. The increase in motional energy is macroscopically linked to an increase of the liquids temperature. As most food has an appreciable water content, microwaves can heat most of the common food, e.g. meat and vegetables. On this basis, the following four questions are discussed in the groups:

- Why does the metallic grid in the ovens front door transmit visible light, but reflects microwaves? As a rule of thumb, the ratio of the wavelength to the diameter of the holes is the key factor.
- For what reason the turntable rotates inside the microwave oven? Due to the reflection of electromagnetic waves at the metallic walls inside the cooking chamber, a standing wave is generated. Without rotation, the food thus is not heated by the microwaves in the nodes of the standing microwave, what leads to a non-uniform temperature pattern.
- How is the high frequency microwave generated? In the so called magnetron, suitable resonant circuits are excited which emit microwave radiation.
- Is a microwave oven an energy saving device? This question is investigated by comparing the input electric power and the deposited thermal energy when heating water.

Cooperation script

To foster the interaction with the learning material we adapted a cooperation script, first proposed by Dansereau (1988) for dyadic cooperation. MURDER is an acronym for the sequence of various phases in cooperation: after the Mood-Phase to establish a positive mind-set for learning, the students studied their expert topic to understand the main ideas and facts. Subsequently, the experts recalled their segment while teaching their jigsaw groups. Afterwards they asked their peers to answer questions for repetition and comprehension, in order to detect problems and elaborate the topic's content and structure. In the concluding Review-Phase the peer students were requested to determine the most relevant keywords relating to the segment they were taught about. In order to match both conditions, the students in the cyclical rotation setting were demanded to answer repetition and comprehension questions and to formulate keywords as well as in the jigsaw classroom.

The learning material provided to the students in order to perform their tasks and to prepare for the test can be downloaded from our homepage¹.

The study

Hypothesis

Basic needs and intrinsic motivation

The students in the expert groups are aware that they have to teach the material to their peers in the jigsaw groups. This teaching expectancy thus should foster an active, deep level interaction with the learning material. Moreover, the student's experience of responsibility for a segment of the material, and of acting as an expert source for other students, is posited to give the student a feeling of competence. In preceding studies, we found that the degree of difficulty of our learning units is well adapted to the students capabilities. Furthermore, there is no anxiety which degrades the learning process, since the students know each other well. In summary, in the jigsaw condition we expect a higher experience of competence as compared to the cyclical rotation setting (Hypothesis 1 a).

Students in the cyclical rotation condition have more leeway in structuring the learning process, since there is no defined time span to interact with a single subtopic. The learning speed can be adjusted by the students in a more appropriate way than in the jigsaw condition. Thus, the students should feel themselves more free, that is, we expect a higher autonomy as compared to the jigsaw condition (Hypothesis 1 b).

In our study, the composition of experts groups as well as cyclical rotation groups was determined by students' self-selection. Thus, in the expert groups as well as

1
2
3
4
5
6 in the station to station groups, the students should feel good with their peers. Due
7
8 to the inherently similar social structure of both methods we expect no difference
9
10 between both conditions regarding the experience of social relatedness
11
12 (Hypothesis 1 c).
13
14

15
16
17 If these hypotheses are confirmed, we expect no difference in intrinsic motivation
18
19 (Hypothesis 2), since, following the self-determination theory, the feeling of
20
21 competence as well as the feeling of autonomy must both be enhanced
22
23 simultaneously by one of the methods to foster intrinsic motivation.
24
25
26
27
28

29 *Academic Performance*

30
31 Regarding the academic performance, two opposite effects might come into play:
32
33

- 34 • We expect advantages on the students' assigned 'expert' segments of
35
36 knowledge in comparison with the cyclical rotation learning. The teaching
37
38 expectancy in the experts group, associated with an intensive interaction with
39
40 the learning material, as well as the subsequent giving of explanations in the
41
42 jigsaw groups, should improve the cognitive structure of the instructing
43
44 student (Springer et al., 1999).
45
46
- 47 • Concerning the segments that the students learned about from fellow group
48
49 members, losses due to reduced information transmission might appear. When
50
51 comparing the jigsaw method to frontal teaching this detrimental effect was
52
53 apparent (Hänze & Berger, 2007).
54
55
56
57
58
59
60

1
2
3
4
5
6 Thus, regarding the overall performance it is not clear which of these both factors
7
8 dominates. For that reason we do not formulate a hypothesis concerning the
9
10 academic performance.
11

12 13 14 15 **Participants, experimental design and procedure**

16
17 20 physics classes (12th grade level), with a total of 286 students,
18
19 participated in the study in the 2003-2004 school year. Originally, the study was
20
21 to be conducted as a cross-over design that investigated the method of instruction
22
23 as both between-subject factor and within-subject factor, although with different
24
25 study topics (Figure 1). Nine classes (Group A) studied the topic ‘scanning
26
27 electron microscope’ in the jigsaw classroom and then were taught the second
28
29 study topic, ‘microwave oven’ in the cyclical rotation method. 11 classes (Group
30
31 B) learned about the first study topic through cyclical rotation teaching and then
32
33 studied the physics of the microwave oven through the jigsaw classroom.
34
35
36
37
38
39
40

41 [Insert Figure 1 about here]
42
43
44

45
46 However, for the second study topic (microwave oven) about a half year later,
47
48 seven classes as well as some students from the remaining classes dropped out
49
50 from our study (a total of 121 students). In order to compensate for this, four new
51
52 classes of 12th graders (58 students) were included. That is, 223 students were
53
54 available for the second study topic. The design was evaluated as a between-
55
56 subjects design for the method of instruction with the study topic as a control
57
58
59
60

1
2
3
4
5
6 factor. Classes were assigned randomly to the jigsaw classroom or the cyclical
7
8 rotation learning condition.
9

10
11
12 First, students were given a test of academic performance (pretest). The actual
13
14 learning unit was made up of four school hours (scanning electron microscope)
15
16 and three school hours (microwave oven), respectively (see Figure 1). Basic
17
18 information on the topics was introduced in two (scanning electron microscope)
19
20 and one (microwave oven) physics hours through direct instruction (same for both
21
22 **methods of instruction**). At the end of these lessons, the learning experience
23
24 questionnaire was given as a pretest measurement. In the following double period
25
26 students in the experimental groups worked in the jigsaw classroom, while the
27
28 other groups studied the same learning material through the cyclical rotation
29
30 method. In the jigsaw classroom, the learning experience questionnaire was
31
32 administered after the work in the expert groups and again when students had
33
34 finished with the jigsaw groups. In the cyclical rotation condition, the learning
35
36 experience questionnaire was given once at the end of the lesson.
37
38
39
40
41
42

43 **For comparison with the cyclical rotation condition, the chosen point in time of**
44 **measurement of the learning experience variables is after working in the expert**
45 **groups. We did not contrast the cyclical rotation groups with jigsaw groups, since**
46 **the main focus of the latter lies on the peer teaching process.**
47
48
49
50
51
52

53 The posttest on academic performance was given in an extra lesson some days
54
55 after the learning unit.

Instruments and measures

Learning experience questionnaire

On the basis of known scales (Prenzel et al., 1993, 2001) we developed a new questionnaire for the following reasons:

- The questionnaire was administered at several points in time. In order not to overstrain the students, the questionnaire needed to be short.
- The items had to be applicable for different learning situations (direct instruction as well as group work).

In the present study, the following scales were used in the German version (cf. Berger & Hänze, 2004). The Cronbach alpha internal consistency reliability for each of the subscales, measured after working in the expert groups and cyclical rotation condition, respectively, is shown in brackets:

Social relatedness ($\alpha=.69$)

SR 1: The atmosphere was pleasant.

SR 2: I felt comfortable with my group.

Experience of competence ($\alpha=.84$)

C 1: I noticed that I really understood things.

C 2: I felt able to master the work.

Experience of autonomy ($\alpha=.54$)

A 1: I had the opportunity to learn about new things on my own.

5
6 A 2: I had a feeling of freedom to make some of my own decisions.
7
8
9

10 Intrinsic motivation ($\alpha=.69$)

11
12 IM 1: I was eager to learn about the material.

13
14 IM 2: The work was really fun.

15
16 IM 3: I didn't notice how the time flew by.
17
18
19
20
21

22 Students respond to the items by using a 5-point, Likert-type scale in which only
23 the first and fifth points are anchored ('strongly disagree' to 'strongly agree').
24
25
26
27

28
29 Additionally, the factor loadings of the basic need items are shown in Table 2. We
30 obtained a clear and interpretable structure of the basic needs items. The
31 extraction is based on a principal component analysis with varimax rotation and
32 three factors, explaining 77.1 % of the variance.
33
34
35
36
37
38
39
40

41 [Insert Table 2 about here]
42
43
44

45 *Academic performance tests*

46
47 The pre- and post performance tests differ from each other, since topic specific
48 questions were included in the posttest. The classification of the test questions
49 (reproduction, reorganisation, and transfer) for each of the topics are up to german
50 school standards set by ministry of education (Leisen, 2004). The tests correlate to
51 the last grade earned in physics to .42 and .45, respectively. The reliabilities of the
52
53
54
55
56
57
58
59
60

1
2
3
4
5
6 tests are $\alpha=.45$ and $.60$, respectively. In consideration of the fact that the four test
7
8 items refer to four different subtopics, these values seem to be satisfactory.
9

10 11 12 **Results**

13
14 We conducted 2 X 2 analyses of variance with the basic needs, intrinsic
15
16 motivation and academic performance as dependent variables and two
17
18 independent variables: method of instruction (jigsaw classroom / cyclical rotation
19
20 learning) and study topic (scanning electron microscope / microwave oven). The
21
22 results are shown in Table 3. Depicted are the adjusted means and standard
23
24 deviations (in brackets). For all variables, corresponding pretest measures were
25
26 used as covariates.
27
28
29
30
31
32
33

34 [Insert Table 3 about here]
35
36
37

38 *Basic needs and intrinsic motivation*

39
40 With regard to the basic needs and the intrinsic motivation no significant
41
42 interaction between method of instruction and topic appeared (see Table 3, right
43
44 column). From that reason we aggregate across both study topics. The results are
45
46 depicted in Figure 2.

56
57
58
59
60

1
2
3
4
5
6 As expected from the theoretical reasoning, with respect to the basic needs both
7
8 methods have different strengths and weaknesses: While the jigsaw classroom is
9
10 favourable concerning the feeling of competence, the students feel more
11
12 autonomous working in the cyclical rotation condition. Following the proposal of
13
14 Cohen (1988), the range of the effect sizes run from small (competence, $d=.24$) to
15
16 medium (autonomy, $d=.39$). We found no difference with regard to the social
17
18 relatedness. Thus, the hypotheses 1 a - c are supported. Additionally, according to
19
20 hypothesis 2 the intrinsic motivation was nearly equal in both settings. In the light
21
22 of the self-determination theory this finding might be interpreted as a
23
24 counteracting effect: the higher experience of competence in the jigsaw classroom
25
26 is balanced by a higher feeling of autonomy in the cyclical rotation setting,
27
28 leading to equal intrinsic motivation. This view is supported by a path analysis
29
30 shown in Figure 3. The experience of competence as well as autonomy mediate
31
32 from method of instruction (jigsaw and cyclical rotation learning, respectively) to
33
34 intrinsic motivation. Furthermore, the path analysis shows that social relatedness
35
36 did not play a crucial rule for motivation.
37
38
39
40
41
42
43
44
45

46 [Insert Figure 3 about here]
47
48
49

50 *Academic Performance*

51
52 Concerning the question, which method of instruction is more favourable
53
54 with regard to performance, we found that it depends on whether the electron
55
56 microscope or the microwave oven was used as the study topic: students working
57
58
59
60

1
2
3
4
5
6 in cyclical rotation groups outperformed the jigsaw groups when learning the
7
8 electron microscope. But when the microwave oven was taught, the jigsaw groups
9
10 performed slightly better (Table 3). Thus the interaction between method of
11
12 instruction and study-topic was significant. The question arises, what causes this
13
14 interaction. A first hint is given by Figure 4: For the jigsaw classroom condition,
15
16 academic performance is divided into expert performance (students' score on that
17
18 part of the test that covered the segment of the learning material assigned to the
19
20 student) and tutored performance (the students' score on that part of the test that
21
22 tested segments a student had learned about from fellow group members).
23
24
25
26
27
28

29 [Insert Figure 4 about here]
30
31
32
33

34 The better performance of the jigsaw groups in the microwave oven learning unit
35
36 is due to the fact, that the tutored performance is equal to the performance in the
37
38 cyclical rotation setting. This is not the case in the electron microscopy learning
39
40 unit. We examine two possible assumptions that might play a crucial role for the
41
42 latter result:
43
44

- 45 1. If the microwave oven learning unit is more easy to comprehend than the
46
47 electron microscope, this should lead to an enhanced feeling of competence
48
49 compared to that experienced in the electron microscope unit. But the
50
51 difference in experiencing competence between both topics is not significant
52
53 (see Table 3).
54
55
56
57
58
59
60

- 1
2
3
4
5
6 2. The students are substantially more interested in the microwave oven learning
7
8 unit ($t(207)=3.42$; $p=.00$). This was assessed with a 19 item scale
9
10 ('Interestingness') provided by Hoffmann et al. (1997). The reliability of the
11
12 scale is $\alpha=.91$. The effect size is estimated to be $d=.48$, that is, a medium
13
14 effect.
15
16

17
18
19
20 In order to test whether the interestingness can be regarded as a mediator between
21
22 topic (that is the scanning electron microscope and the microwave oven,
23
24 respectively) and achievement in the tutored segments (cf. Figure 5), we follow
25
26 the proposal by Baron & Kenny (1986).
27
28
29
30
31

32 [Insert Figure 5 about here]
33
34
35

36 They recommend to accomplish a series of three regression equations
37
38 (unstandardized regression coefficients, standard errors in brackets):
39
40

- 41 1. Tutored performance is used as the criterion and topic as the predictor²:
42
43 $c=.082$ (.030); $p=.008$
44
45
46 2. Interestingness is used as the criterion variable and topic as the predictor:
47
48 $a=.315$ (.091); $p=.001$
49
50
51 3. The tutored performance is used as the criterion variable and interestingness
52
53 as well as topic as predictors: $b=.057$ (.023); $p=.016$ and $c'=.064$ (.031);
54
55 $p=.039$.
56
57
58

59 _____
60 ² Additionally, the pretest measure for performance was included as predictor in all analyses.

1
2
3
4
5
6 That is, when controlling for the mediator, the beta-weight from topic to
7
8 performance is decreased from .082** to .064*. Running the SOBEL-Test as
9
10 proposed by Preacher & Hayes (2004) it is shown that this decrease is statistically
11
12 significant on a .05 level³. Following Baron & Kenny, the link from topic over
13
14 interestingness to tutored performance thus is a partial mediator.
15
16
17
18
19

20 Discussion

21
22 On the basis of Deci and Ryans self-determination theory we assessed two
23
24 small-group settings, the jigsaw classroom and cyclical rotation learning. Both
25
26 methods show characteristic advantages particularly with regard to its capabilities
27
28 in fostering the experience of autonomy and competence. On the one hand, the
29
30 students feel less autonomous when working in the jigsaw classroom. The benefits
31
32 of the cyclical rotation method with regard to the experience of autonomy might
33
34 result from the more open structure. For example, in the jigsaw classroom a
35
36 deadline for working in the expert groups is defined. This might derogate the
37
38 experience of autonomy. On the other hand, the teaching expectancy in the expert
39
40 groups might stimulate an intensive interaction with one segment of the topic,
41
42 what should favour the experience of competence. This is particularly interesting
43
44 in light of the frequently espoused position that teaching expectancy might lead to
45
46 anxiety and thus a degradation of intrinsic motivation: most of the students
47
48 participating in the study seem to be familiar with giving explanations to their
49
50 peers. Furthermore, this is accompanied by a pronounced feeling of relatedness.
51
52
53
54
55
56
57

58
59 ³ Calculated online from <http://www.psych.ku.edu/preacher/sobel/sobel.htm> (Retrieved February
60 15th, 2007).

1
2
3
4
5
6 Due to the similar structure of both learning methods no noticeable difference can
7
8 be observed regarding social relatedness. Concerning the intrinsic motivation no
9
10 appreciable difference is observed. As suggested by a path analysis this comes
11
12 about because two opposing factors, autonomy and competence, balance each
13
14 other. This is in accordance with the self-determination theory which states, that
15
16 the experience of competence as well as autonomy have to be fostered to enhance
17
18 motivation (Deci & Ryan, 2000). Furthermore the path analysis shows that the
19
20 social relatedness plays no significant role for the intrinsic motivation. This point
21
22 is discussed controversially in the literature.
23
24
25
26
27
28

29
30 Regarding academic performance no main effect of method of instruction was
31
32 found when aggregating across both study topics electron microscope and
33
34 microwave oven. This is in accordance with the results from a study conducted by
35
36 Hidi et al. (1998): **after initial classroom instruction the students worked in a**
37
38 **science center in small group settings. The authors did not find differences in**
39
40 **posttest academic performance between jigsaw and the cyclical rotation method.**
41
42

43
44 In our study a significant interaction indicates that performance depends on the
45
46 study topic (cf. Table 3). With respect to the unit 'scanning electron microscope',
47
48 the cyclical rotation method outperformed the jigsaw classroom, whereas an
49
50 opposed trend is observed with regard to the microwave oven learning unit. This
51
52 is due to the better results in the part of the test covering areas of the material that
53
54 jigsaw participants had been taught by fellow group members. We elucidated the
55
56 interestingness of the study topics as a partial mediator between method of
57
58
59
60

1
2
3
4
5
6 instruction and performance: a higher interestingness might lead to an enhanced
7
8 arousal during instruction in the jigsaw groups. Furthermore, an appealing study
9
10 topic should foster a more intensive study of the learning material at home.
11

12
13 Nevertheless, it seems clear that the observed discrepancy cannot be ascribed to a
14
15 single factor. This question needs further research.
16

17
18 Due to the design of the study, the observed effects can not clearly be traced back
19
20 to one of the factors teaching expectancy, giving explanations or resource
21
22 interdependence. In a subsequent study these factors are investigated separately,
23
24 what should explain their relative meaningfulness.
25
26

27
28 With regard to the jigsaw method further research is needed on how to improve
29
30 the knowledge transmission from the experts to novices. It probably might be
31
32 helpful if future research would focus stronger on investigating mediating links
33
34 between the method of instruction and learning outcomes. This will give further
35
36 insight into specific benefits and drawbacks of teaching methods and helps to
37
38 abandon the fruitless discussion about “the best method”.
39
40

41
42 The results of the present study might give teachers valuable hints for the choice
43
44 of the appropriate method, best suited to the teaching objectives. If the difficulty
45
46 of the group task is well adapted to the students' cognitive level the jigsaw
47
48 classroom is a powerful method in promoting the experience of competence,
49
50 especially for students with below average physics related self-concept (cf. also
51
52 Hänze & Berger, 2007).

Note. ^ain percent of maximum score. The degree of freedom for all variables is df=(1; 443).

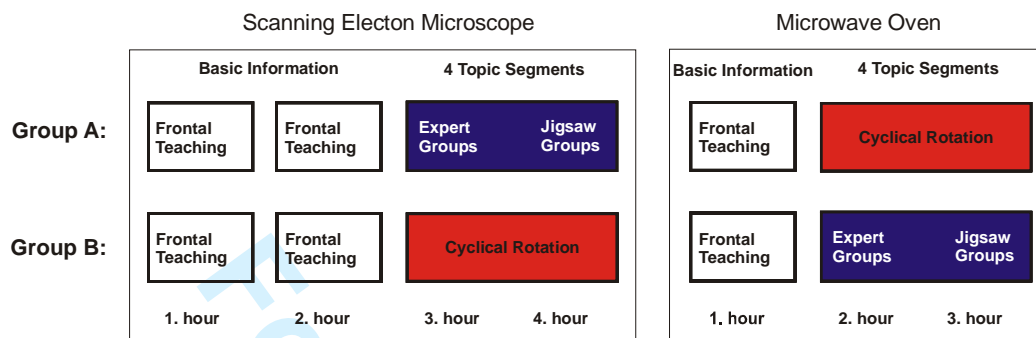

Figure 1. Design of the study.

Figure 2. Adjusted means of the Basic Needs and intrinsic motivation aggregated across both topics. For all variables, corresponding pretest measures were used as covariates. The effect size (Cohen's d) is depicted in brackets. (**: <.01; *: <.05).

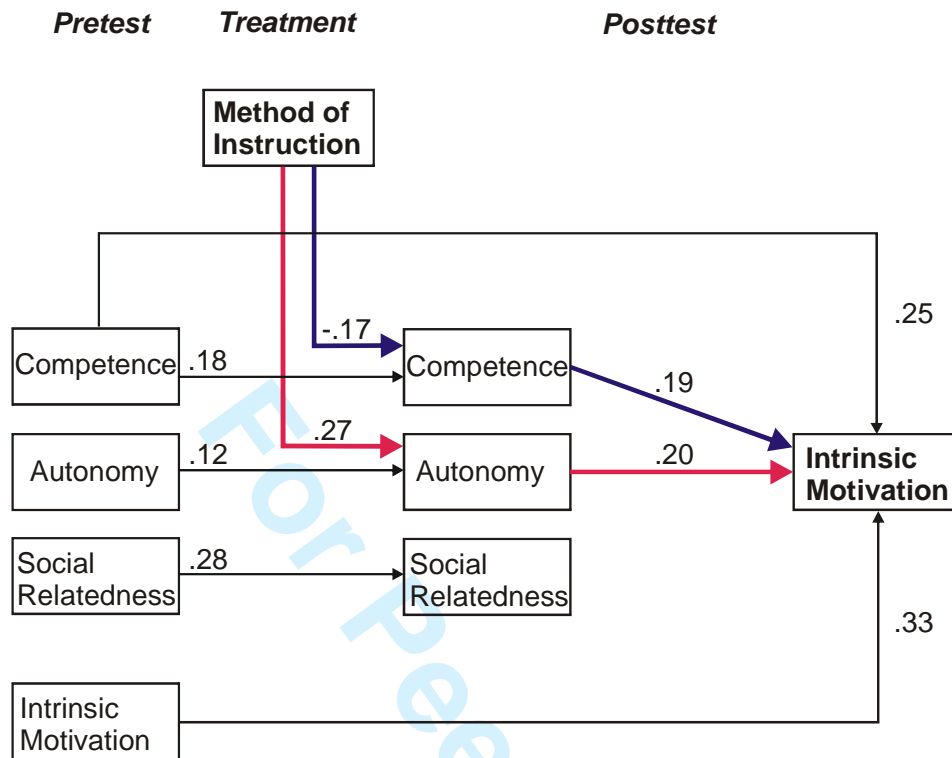

Figure 3. Path-analytic model: Influence of method of instruction on intrinsic motivation mediated by the basic needs. Jigsaw classroom and cyclical rotation are coded as 1 and 2, respectively. Only the significant paths are depicted. The results from the pretest measurement are included to control for preexperimental differences. ($N=375$, $\chi^2(1)=0.97$, $p=.32$, $RMSEA=0.0$, $R^2=.26$).

Figure 4. Performance in Percent of maximum score. The depicted means are adjusted by the pretest covariate.

Figure 5. Model for testing the question if the interestingness is a mediator between topic and tutored performance.
