ABSTRACT: In this paper a cognitive community-based analytic framework is established to investigate intra-cluster knowledge diffusion. The results from both a case study on a sock manufacturing cluster in China and an agent-based simulation indicate that the initial pattern of knowledge distribution has a significant impact on the process of knowledge diffusion in a cluster. A cluster with a higher knowledge level but lower knowledge heterogeneity enjoys higher efficiency of knowledge diffusion.

La diffusion de la connaissance au sein de
la grappe d'industries de la chaussette à Datang en Chine.

Zhang et al.

Cet article cherche à construire une structure analytique cognitive basée sur la communauté afin d'examiner la diffusion de la connaissance au sein des grappes. Les résultats qui proviennent d'une étude de cas d'une grappe d'industries de la chaussette en Chine et d'une simulation basée sur un agent laissent indiquer que dans un premier temps la distribution de la connaissance influe sensiblement sur le processus de diffusion de la connaissance en grappes. Une grappe dotée d'un niveau de connaissance plus élevé mais d'une connaissance hétérogène moins élevée jouit d'une diffusion de la connaissance plus efficace.

Wissensdiffusion innerhalb des Clusters der Strumpfersteller von Datang in China

Gang Zhang, Qian Xu and Xiaming Liu

ABSTRACT

In diesem Beitrag wird ein kognitiver, gemeinschaftsgestützter analytischer Rahmen zur Untersuchung der Wissensdiffusion innerhalb von Clustern geschaffen. Aus den Ergebnissen der Fallstudie eines Clusters von Strumpfhernherstellern in China und einer aktorbasierten Simulation geht hervor, dass sich das anfängliche Muster der Wissensweitergabe signifikant auf den Prozess der Wissensdiffusion in einem Cluster auswirkt. In einem Cluster mit höherem Wissensniveau, aber niedrigerer Wissensheterogenität wird das Wissen effizienter diffundiert.

Divulgación del conocimiento en la aglomeración manufacturera de calcetines de Datang en China

Gang Zhang, Qian Xu and Xiaming Liu

ABSTRACT

En este artículo establecemos una estructura analítica cognitiva basada en la comunidad para investigar la divulgación intracumular del conocimiento. Los resultados de un estudio de caso sobre una aglomeración manufacturera de calcetines en China y una simulación basada en agentes indican que el modelo inicial de la distribución del conocimiento tiene un efecto importante en el proceso de divulgación de conocimiento en una aglomeración. Una aglomeración con un nivel más alto del conocimiento pero una menor heterogeneidad es mucho más eficaz para divulgar el conocimiento.

5 (2) INTRODUCTION
6

7 Intra-cluster knowledge diffusion has long been recognized as an important
8
9 source of the competitiveness of industrial agglomeration (MARSHALL, 1920;
10
11 MASKELL and MALMBERG, 1999; MASKELL, 2001a, 2001b; BRESCHI and
12
13 LISSONI, 2001). The research on this topic has used two alternative perspectives –
14
15 geographic proximity and non geographic proximity (GERTLER, 2003; BOSCHMA,
16
17 2005). The geographic proximity perspective argues that tacit knowledge can only be
18
19 transferred by face-to-face interactive learning. The closer two firms are located, the
20
21 more effective the tacit knowledge transfers, so that a cluster is efficient in knowledge
22
23 absorption and creation (DESROCHERS, 2001; PORTER, 1990; JAFFE et al., 1993;
24
25 FLORIDA, 1995; AUDRETSCH and FELDMAN, 1996; MASKELL and
26
27 MALMBERG, 1999; TALLMAN et al., 2004). On the other hand, the non geographic
28
29 proximity perspective stresses the effect of relational or social proximity on
30
31 knowledge diffusion between firms. It argues that as firms in a cluster have a certain
32
33 type of relational proximity, they can communicate knowledge efficiently between
34
35 them (CAPELLO and FAGGIAN, 2005; CREVOISIER, 2004; KEEBLE and
36
37 WILKINSON, 1999).
38
39
40
41
42
43
44
45
46
47
48

49 Though these two perspectives lay a concrete foundation for an understanding of
50
51 regional diffusion of knowledge, one problem is that they consider meso-level
52
53 variables only and are unable to explain the uneven diffusion of knowledge in a
54
55 cluster effectively. This may be the reason why scholars have recently started
56
57 examining the role of some micro-level variables of firms in knowledge diffusion
58
59
60

1
2
3
4 (BOSCHMA and WAL, 2006; OWEN-SMITH and POWELL, 2004; GIULIANI
5
6
7 and BELL, 2005; GIULIANI, 2005) .
8

9
10 Focusing on the knowledge structure, one of the firm-specific variables, this
11
12 paper aims to examine the phenomenon of knowledge diffusion within Datang, a sock
13
14 manufacturing cluster from the Yangtze River Delta, China. Methodologically, we
15
16 combine a cross-section case study and a longitudinal simulation to investigate both
17
18 the static and dynamic nature of technological and business knowledge learning and
19
20 diffusion within a cluster.
21
22
23
24

25
26 YIN (2003) suggests that case studies should start with theoretical propositions.
27
28 In the next section, we establish a cognitive community-based analytic framework for
29
30 intra-cluster knowledge diffusion by using the concept of scheme from social
31
32 cognition. It argues that a cognitive community formed through the cognitive
33
34 proximity between firms is the fundamental method of knowledge diffusion in the
35
36 cluster, so that only those firms with similar knowledge structures would be efficient
37
38 in learning and transferring knowledge.
39
40
41
42

43
44 In section 3, the evidence from our case study of 8 firms indicates that the
45
46 technological knowledge distribution in Datang is relatively homogeneous (i.e. firms
47
48 belong to a proximate cognitive community), and hence there is fluent and efficient
49
50 local learning and diffusion of such knowledge. On the other hand, business
51
52 knowledge distribution is heterogeneous, and such knowledge diffusion is rare.
53
54
55
56

57
58 Our analytical framework is tested and confirmed not only by the case study, but
59
60 also the simulation as presented in section 4. This simulation shows that the initial

1
2
3
4 pattern of knowledge distribution has a significant impact on the process of
5
6
7 knowledge diffusion in a cluster. A cluster with a higher knowledge level but lower
8
9
10 knowledge heterogeneity enjoys higher efficiency of knowledge diffusion. In section
11
12 5, we summarise our findings and discuss the implications as well as limitations of
13
14
15 this study.

16 17 18 19 2. THEORETIC FRAMEWORK

20
21 It is generally accepted that the efficiency of intra-cluster knowledge diffusion is
22
23 very important for the competitiveness of a cluster. Knowledge diffused in a cluster is
24
25 often classified into two categories: tacit or codified (MASKELL, 2001a; PINCH et al,
26
27 2003). According to this classification, two alternative perspectives, geographic
28
29 proximity and non geographic proximity, have emerged. Although these perspectives
30
31 emphasise the different factors influencing intra-cluster knowledge diffusion, they
32
33 both have an implicit assumption that firms in a cluster are homogenous, and what
34
35 determines the efficiency of knowledge diffusion among firms is the similarity of
36
37 some meso-level variables such as geography, culture and relationship (BOSCHMA,
38
39 2005).
40
41
42
43
44
45
46
47

48 It has recently been realised that some micro- or firm-specific variables also play
49
50 a critical role in intra-cluster knowledge diffusion. For instance, OWEN-SMITH and
51
52 POWELL (2004) emphasise the influence of a firm's social role in knowledge
53
54 diffusion in a cluster. GIULIANI (2005), GIULIANI and BELL (2005) and
55
56 BOSCHMA and WAL (2006) all argue that the absorptive capacity of firms in a
57
58 cluster affects the knowledge exchange among them and that the difference in the
59
60

1
2
3
4 firms' absorptive capacity leads to a heterogeneous distribution of knowledge in the
5
6 cluster. Although such micro-variable focused studies help deepen our understanding
7
8 of the phenomenon of intra-cluster knowledge diffusion, so far not enough attention
9
10 has been paid to a firm's knowledge structure, another important micro-variable. In
11
12 our view, the efficiency of knowledge diffusion between firms may be dependent
13
14 more on whether the knowledge fits into their knowledge structures than what type of
15
16 knowledge is diffused (tacit or codified). To some extent, a cluster's cognitive
17
18 community formed by the similarity of knowledge structures determines the
19
20 efficiency of knowledge diffusion within it.
21
22
23
24
25
26
27

28 From the view of firms in a cluster, cognitive proximity may be the necessary
29
30 condition for knowledge diffusion between firms in it, and a cluster's efficiency of
31
32 knowledge diffusion may depend on its distribution of knowledge. Borrowing the
33
34 concept of schema from social cognition, we start by explaining the meaning of the
35
36 term "knowledge structure of a firm in a cluster", and then develop our cognitive
37
38 community-based analytic framework.
39
40
41
42

43
44 The perspective of cognition stresses the impact of an agent's existing knowledge
45
46 structure on his/her perceiving, interpreting, analyzing and remembering the
47
48 information received (WALSH, 1995). One of the most important concepts of
49
50 cognition used in the area of psychology, sociology and management is schema
51
52 (BARTUNEK, 1984; GIOIA and POOLE, 1984; LORD and KERNAN, 1987;
53
54 HARRIS, 1994; RENTSCH and KLIMOSKI, 2001; WOEHR and RENTSCH, 2003).
55
56 Schema is a sort of cognitive knowledge structure, representing "knowledge about a
57
58
59
60

1
2
3
4 concept or type of stimulus, including its attributes and relations among those
5
6
7 attributes” (FISKE and TAYLOR, 1991, p.98). Social psychologists have identified
8
9
10 numerous groups of schema, the main ones including: person schemas, self-schemas,
11
12 role schemas and event schemas. Existing studies show that schemas enable us to
13
14 efficiently code and categorise information, and influence what we pay attention to
15
16 and what we ignore, and what we remember about a social situation.
17
18

19
20 The concept of schema from social cognition may be useful in interpreting the
21
22 influence of firms’ knowledge structures on the process of knowledge diffusion
23
24 between them. In the view of cognition, the knowledge structure of a firm determines
25
26 not only its absorptive capacity but also its information processing procedure,
27
28 including perceiving, encoding, memorizing and inferring. As knowledge about any
29
30 stimulus can be schematized, individuals have numerous schemas at their disposal
31
32 (RUMELHART, 1984). According to this, HARRIS (1994) uses concepts such as
33
34 organisation schema and object schema to investigate the impact of organizational
35
36 culture upon individual sense-making. What kinds of schema are most relevant to
37
38 understanding intra-cluster knowledge diffusion? Given that technological and
39
40 business knowledge are the most exchanged in a cluster and are the most important
41
42 factors for the development of firms, we propose that a firm’s knowledge structure is
43
44 comprised of two types of schema¹: technological schema and business schema.
45
46
47 These schemas capture the range of knowledge a firm uses to make sense of
48
49
50
51
52
53
54
55
56
57
58
59
60 knowledge diffused in a cluster.

(1) *Technological schema*. Technological schema refers to a firm’s knowledge

1
2
3
4 concerning the concepts and processes of a certain type of technology. It includes not
5
6 only the knowledge about what the technology is but also the evaluation and opinion
7
8 about the technology. For instance, television producers may have different
9
10 technological schemas on the high-definition technology. Some may know much
11
12 about the LCD technology and rate it more promising and others may know more
13
14 about PDP technology and think it superior to LCD. Apart from the concept and
15
16 opinion of a technology, technological schemas include technological scripts, which
17
18 describe a firm's knowledge about expected event sequences and appropriate
19
20 operation in using the technology.
21
22
23
24
25
26
27

28 (2) *Business schema*. Business schema refers to the knowledge of concept and
29
30 process about management and marketing in a firm's daily operation. For a firm,
31
32 business schemas may include knowledge about how to do international marketing,
33
34 how to manage workshops, and how to keep good relations with employees.
35
36
37

38 Once schemas have been established, they influence a firm's information
39
40 processing in two ways:
41
42

43
44 (1) *Schema-driven effect*. Schemas guide the search for, acquisition and
45
46 processing of information, and subsequent behaviour in response to that information.
47
48 As people are limited in their ability and capacity to process information, schemas
49
50 offer simplified ways to code and categorise new information, without the need to
51
52 start from a blank sheet every time (FISKE and TAYLOR, 1991; PENNINGTON,
53
54 2000).
55
56
57
58

59 (2) *Perseverance effect*. Schemas that have become established and developed
60

1
2
3
4 from a great deal of experience may be quite resistant to change with pressure to
5
6 maintain the status quo (FISKE and TAYLOR, 1991). That is, previously formed
7
8 beliefs tend to persist even in the face of contradictory evidence.
9
10

11 Firms with similar schemas belong to a cognitive community (or schematic
12
13 community). The similarity of schema articulates that commonality among the firms'
14
15 schemas will be characterized by incomplete overlap (WOEHR and RENTSCH, 2003)
16
17 as they will not be identical. Therefore, schema similarity refers to the degree to
18
19 which firms in a cluster have similar or compatible knowledge structures for
20
21 organizing and understanding cluster-related phenomena. The schema similarity
22
23 consists of two components: schema congruence and schema accuracy. Schema
24
25 congruence exists when firms' schemas are compatible in content and/or structure.
26
27 For example, if firms A and B's schemas of client services contain 'delivery in time',
28
29 then their schemas of client services have some degree of congruence. Schema
30
31 accuracy refers to the degree to which a firm's schema is similar to a 'true score' or
32
33 target (RENTSCH and KLIMOSKI, 2001). For example, firm A's schema of firm B's
34
35 adherence to customers' value is accurate when B actually believes that the adherence
36
37 to customers' value is very important.
38
39
40
41
42
43
44
45
46
47
48
49

50 As schemas become more complex, they may develop into some sub-schemas.
51
52 Firms in the same type of cognitive community will fall into different sub-cognitive
53
54 communities by their development stages of schemas (see Fig. 1).
55
56
57
58
59
60

Fig. 1. The Classification of Cognitive Community²

<Fig 1 about here>

1
2
3
4 The concept of cognitive community is more focused on the similarity of
5
6
7 knowledge structure, and this is different from the concepts of community or
8
9
10 community of practice often used by some researchers. A cognitive community is not
11
12 an observable or real entity, and lacks a definite object or structure as a community
13
14 and community of practice, so that even the members of a cognitive community may
15
16
17 not be aware of their own membership.
18

19
20 As a firm's schemas influence its whole information processing procedure
21
22 (including perceiving, encoding, memorizing and inferring), a cognitive community
23
24 formed by schematic similarity has two important effects on intra-cluster knowledge
25
26
27 diffusion:
28

29
30
31 (1) *Cognitive community's blocking effect on knowledge diffusion.* As soon as
32
33 they have been established, schemas take place in a firm's information processing
34
35 procedure. Firms with a similar (or the same) type of schema enjoy higher efficiency
36
37 of knowledge diffusion than firms with different types of schema. Given the
38
39 schema-driven effect, a firm is more sensitive to the information most relevant to its
40
41 schema, and may ignore other information. The priming effect also shows that a
42
43 schema activated recently is most likely to be reactivated (FISKE and TAYLOR 1991).
44
45
46 As firms are limited in their ability to process information, and as the information
47
48 received is often fragmentary and passing, without the help of schemas firms can
49
50
51 hardly make sense of any information circulated in a cluster. Only firms with similar
52
53
54 schemas can exchange knowledge through such fragmentary and passing information.
55
56
57
58
59
60 COWAN et al. (2000) argue that, as some of the knowledge diffused is highly

1
2
3
4 complex, only a knowledge sender and receiver with the same codebook can
5
6
7 communicate well with each other. The schema in our framework is equivalent to the
8
9
10 codebook. With a similar schema, knowledge flows within channels of this specific
11
12
13 cognitive community. In this sense, there is a blocking effect on knowledge diffusion
14
15
16 between firms with different schemas.

17
18 (2) *Cognitive community's filtering effect on knowledge diffusion.* A filtering
19
20 effect takes place between sub-cognitive communities within a general cognitive
21
22
23 community at different development stages. As schemas become more complex, they
24
25
26 may develop into some sub-schemas. Even for sub-schemas of the same type, their
27
28
29 degrees of precision are different by their stages of development, which affects firms'
30
31
32 information processing efficiency and speeds (FISKE and TAYLOR, 1991; COWAN
33
34 et. al, 2000). Firms with less developed (or coarser) schemas sometimes may not
35
36
37 understand the information diffused from firms with well-developed (or finer)
38
39
40 schemas. It is equivalent to what happens in computer software development: an old
41
42
43 edition of word processing software cannot be used to read or edit a file produced by a
44
45
46 new edition, but the new version can be used to edit either version of the file. REED
47
48
49 and DEFILLIPPI's (1990) study on imitation between firms in an industry also shows
50
51
52 that the difference in the stage of knowledge development raises the barrier to
53
54
55 imitation.

56
57
58 Obtaining the membership of a cognitive community by schema similarity, firms
59
60
intra-cluster knowledge diffusion behaves in a cognitive community-based style. In

1
2
3
4 fact, because of the difference in firm knowledge structure, knowledge is not diffused
5
6
7 evenly in a cluster. Fig. 2 presents an illustration of cognitive community-based
8
9
10 intra-cluster knowledge diffusion.

11
12
13
14
15 ***Fig. 2. The Cognitive Community-based Intra-cluster Knowledge Diffusion***

16
17
18 <Fig 2 about here>

19
20
21
22
23 In Fig. 2, firms A and B are assumed to be classified into different cognitive
24
25 communities due to their schema similarity patterns. Firm A is a member of the
26
27 technological cognitive community (T1-4)³ and business cognitive community (B1-4),
28
29 (B3-4), and firm B is a member of the technological cognitive community (T4-3) and
30
31 business cognitive community (B1-1), (B3-4). As firms A and B belong to different
32
33 types of technological community (T1-4) (T4-3), knowledge diffusion between them
34
35 is not efficient due to a cognitive community's blocking effect. In other words, firm A
36
37 can hardly learn the knowledge in the cognitive community (T4-3) from firm B, and
38
39 vice versa.
40
41
42
43
44
45

46
47 What happens in the business cognitive communities represents both the blocking
48
49 effect and filtering effect. As firms A and B belong to the business cognitive
50
51 communities (B1-4), (B3-4) and (B1-1), (B3-4) respectively, both are members of a
52
53 cognitive community of the same type, and the only difference between them is their
54
55 development stages of schema. Firm A in the business cognitive community B1 has a
56
57 more developed schema than firm B, and firms A and B have schemas at a similar
58
59
60

1
2
3
4 development stage in business cognitive community B3. The different business
5
6
7 knowledge structures of firms A and B make knowledge diffusion between them
8
9
10 asymmetric. Firm A may be more efficient than B in learning by a cognitive
11
12 community's filtering effect in business cognitive community B1. However, in
13
14
15 business cognitive community B3, both firms can diffuse knowledge with efficiency
16
17
18 as they have schemas at a similar development stage. It needs to be noticed that the
19
20
21 existence of a cognitive community's blocking effect may prevent the firms from
22
23
24 enjoying high efficiency of technological knowledge diffusion in other business
25
26
27 cognitive communities (such as B1) even though they are both the members of a
28
29
30 highly developed cognitive community (B3).

31
32 To sum up, our cognitive community-based analytic framework for intra-cluster
33
34 knowledge diffusion argues that the cognitive community formed through the
35
36
37 cognitive proximity between firms is the fundamental way of knowledge diffusion in
38
39
40 the cluster, so that only those firms who have a similar knowledge structure will be
41
42
43 efficient in learning and transferring knowledge. In addition, on the cluster level,
44
45
46 knowledge distribution of a cluster has a critical effect on knowledge diffusion within
47
48
49 it. In a cluster with highly homogeneous firms' knowledge structures, knowledge
50
51
52 diffusion would be active, as most firms belong to proximate cognitive communities.
53
54
55 On the contrary, in a cluster with highly heterogeneous firms' knowledge structures,
56
57
58 knowledge diffusion would be inactive and knowledge would flow in an uneven way,
59
60
61 as most firms are located in the many scattered cognitive communities and knowledge
62
63
64 transfer across communities is difficult.

3. CASE STUDY

Since the 1990s, a number of industrial clusters have emerged in China where thousands of firms in related industries have agglomerated. Among industrial clusters in China, the most remarkable ones are located in the Pearl and Yangtze River Deltas. The former Delta focuses on electronics, communication equipment and chemicals and the latter on textiles and home appliances. Industrial clusters in these two areas are highly competitive in both the home and overseas markets (ZHANG et al., 2004; ENGARDIO and DEXTER, 2004). Zhejiang Province is located in the southern part of the Yangtze River Delta, which covers a total land area of 101,800 square kilometers. There are 11 cities under the direct jurisdiction of the Zhejiang provincial government, including Hangzhou, Ningbo, Wenzhou, Jiaxing, Huzhou, Shaoxing, Jinhua, Quzhou, Zhoushan, Taizhou and Lishui, under which there are 36 counties, 22 town-level cities and 30 county-level districts. As one of the most economically vibrant and developed provinces, Zhejiang ranks fourth in China in terms of overall economic output, and the economy is characteristic of hundreds of industrial clusters in various industries, such as textiles, garment, socks, ties, auto parts, plastics and mould. According to the Zhejiang Statistical Yearbook 2007, the economic output of these industrial clusters has made up approximately 50 per cent of the province's GDP in 2006. As the Datang Sock Cluster (DSC) in Shaoxing City of Zhejiang Province is representative of traditional industrial clusters in China, the case study on it would provide some insights into the underlying causes of the competitiveness of China's traditional industrial clusters, and even for similar traditional clusters in other

1
2
3
4 countries.

5
6
7 In this section, to further explore and verify the cognitive community-based
8
9 analytic framework presented above, we report a case study of eight representative
10
11 firms in the DSC. Table 1 summarises the major characteristics of the firms. The
12
13 identities of these firms are disguised to ensure confidentiality.

14
15
16
17 Three factors were considered for the case selection. Firstly, cases were in industrial
18
19 clusters with strong competitive capabilities. Secondly, firms were representative in
20
21 size, from small to medium and large. Thirdly, for the data stability, only firms which
22
23 had been in operation for at least three years would be chosen.
24
25
26

27
28 Although the sock production industry is less knowledge intensive than the
29
30 electronics, telecommunication and biotechnology industries, a study of knowledge
31
32 diffusion in this industry is still valuable. It is undeniable that low labour cost is an
33
34 important element of competitiveness for traditional low-technology and
35
36 low-knowledge intensive clusters. However, considering the fact that every region in
37
38 China enjoys such advantage, it is hard to explain why most of the competitive
39
40 clusters have only emerged in limited places such as the Pearl and Yangtze River
41
42 Deltas and not evenly throughout the nation. Factors other than labour cost may have
43
44 had an important effect on the success of such traditional clusters. In our view,
45
46 competitive advantage of Chinese traditional clusters does not depend merely on low
47
48 labour cost. Rather, knowledge may be crucial. PORTER (1998) argues that “there is
49
50 no such thing as a low-tech industry. There are only low-tech companies”. Although
51
52 the sock industry is traditionally labour-intensive, there are extensive knowledge
53
54
55
56
57
58
59
60

1
2
3
4 learning and diffusing activities, and business knowledge may be more important for
5
6
7 a study of traditional industries. Actually, studies on traditional industries by
8
9
10 BOSCHMA and WAL(2006), BELL and ALBU (2005) and GIULIANI (2005) have
11
12 proved this.

13
14
15 The Datang Sock Cluster is in Datang, a small town in eastern Zhejiang Province.
16
17 Sock production is the pillar industry of Datang. There are more than 10,000 sock
18
19 makers in the town at present, with more than 200,000 employees. There are about
20
21
22 100,000 sock-knitting machines in Datang, including more than 40,000 top grade
23
24
25 computer knitting machines and 20,000 associated facilities. DSC holds a very
26
27
28 important position both in the Chinese and global sock-making industry (ZHANG et
29
30
31 al., 2004; LEE, 2005; DATANG TOWN GOVERNMENT, 2005). According to the
32
33
34 statistics from Macrochina Database published by the Chinese National Bureau of
35
36
37 Statistics, China produced about 18 billion pairs of socks, among which Datang
38
39
40 produced 12 billion pairs, accounting for 67 per cent of total domestic and 35 per cent
41
42 of global output in 2004.

43
44
45 Sock-making in Datang can trace its history back to the 1930s, when a few
46
47
48 craftsmen produced socks with manual sock machines in their homes to meet local
49
50
51 needs. The development of the modern sock industry in Datang has gone through
52
53
54 three stages. Between the 1970s and the mid-1980s, with the transition of the planned
55
56
57 economy, some town- and village-owned sock factories were established, including
58
59
60 Chaota, Zhongjia, Anhua and Chenshan Sock Factory. From the mid-1980s to the
mid-1990s, with the deepening of economic reforms in China, most township and

1
2
3
4 village-owned sock factories gradually went bankrupt and privatized, and many
5
6
7 former workers began to run their own household sock-making factories on a small
8
9
10 scale. From the mid-1990s to present, there have emerged many firms with large scale
11
12 production among these household factories. Currently, sock firms in Datang can be
13
14 classified into two types in terms of size: large (and medium) enterprises and small
15
16 manufacturers. Large enterprises usually have the capability of large scale production,
17
18 but they don't invest in the whole production process of sock-making. They are
19
20 mainly concerned with obtaining big orders from foreign buyers such as Wal-Mart or
21
22 Carrefour. After getting these orders, they subcontract to small manufacturers who
23
24 produce semi-finished socks for them, and then accomplish the final stage of
25
26 production such as packing. On average, a large enterprise will have about 20 to 30
27
28 small manufacturers to fulfill orders, and a small manufacturer would have to act as a
29
30 supplier for one or more large/medium enterprises. Small manufacturers account for
31
32 approximately 90 per cent of the total number of sock firms in Datang.
33
34
35
36
37
38
39
40
41
42

43 3.1 Data Collection and Codification

44 3.1.1 Data Collection

45
46
47 We conducted in-depth interviews with the general or deputy general managers
48
49 and chief engineers of the eight firms listed in table 1. Each interview lasted for about
50
51 one and a half hours on average. Interviews were tape-recorded unless the informants
52
53 objected. To assure the accuracy of the interview data, we conducted member checks
54
55 (YIN, 1981; YAN and GARY, 1994). All the interviews were conducted during
56
57
58
59
60 October and November 2006. In addition to interviews, approximately 30 pages of

1
2
3
4 archival data were collected for each firm, including the information about the firm's
5
6
7 history, strategies, and main clients.
8
9

10
11
12 ***Table 1. Summary of the Major Characteristics of the Firms⁴***
13

14
15 <Table 1 about here>
16
17

18 19 20 3.1.2 Data Coding 21

22
23 Data from the interviews and archives were coded using content analysis
24
25 methods. Firstly, we coded all data into a number of categories according to the
26
27 proposed theoretical framework. These categories are (1) type of technology, (2) level
28
29 of technology, (3) technological development strategy, (4) market orientation, (5)
30
31 market development ability, (6) business strategy, (7) channels for acquiring
32
33 technological knowledge, and (8) channels for acquiring business knowledge.
34
35
36
37

38
39 Secondly, we created subcategories according to the characteristics of the above
40
41 categories. For example, three subcategories: international market, home market, and
42
43 local market, were grouped into "market orientation". Table 2 shows an example of
44
45 data coding for one of the eight firms.
46
47
48
49
50

51
52 ***Table 2. Examples of Data Coding⁵***
53

54
55 <Table 2 about here>
56
57

58
59
60 Data coding was completed by three team members participating in the

1
2
3
4 interviews. We jointly developed the coding category in the first stage and used it to
5
6
7 code one case. Then, the three team members each specialised in coding, auditing and
8
9
10 checking for the remaining seven cases. The auditing and checking consisted of two
11
12 steps: the confirmation and double checking of data coding.
13

14 15 16 3.2 Results 17

18
19 Our study on the DSC shows that knowledge distribution of a cluster has a
20
21 significant influence on knowledge diffusion within it. Firms in DSC have a high
22
23 degree of homogeneity in technological knowledge, and are located within a
24
25 proximate cognitive community. In conformity with our cognitive community-based
26
27 analytic framework, the knowledge diffusion between firms is very active and
28
29
30 knowledge flows mainly in the local area. Contrary to the case of technological
31
32
33 knowledge, firms in DSC have a high degree of heterogeneity in business knowledge
34
35 so that it is hard for knowledge diffusion between firms to take place intentionally or
36
37 non-intentionally, so that knowledge flows suffer from stickiness.
38
39
40
41

42
43 DSC also shows that the combination of similarity in technological knowledge
44
45 and divergence in business knowledge facilitates local flexible production and
46
47 contributes to the competitiveness of the cluster. For technological knowledge,
48
49
50 homogeneity guarantees that a sufficient number of local firms will participate in the
51
52 related sectors and fulfill re-allocated orders. For business knowledge, heterogeneity
53
54 ensures that only a few firms have the ability to integrate local flexible production to
55
56
57 achieve economies of scale and efficiency.
58
59
60

3.2.1 Knowledge Distribution of Firms in DSC

From the case studies it can be seen that the knowledge structures of firms in DSC were neither purely heterogeneous nor completely homogeneous, because the distribution of technological and business knowledge exhibited different patterns. Fig. 3 indicates that the sample firms are highly similar in the technology but significantly different in the business dimension.

Fig. 3 The Distribution of Knowledge Structure in DSC⁶

<Fig 3 about here>

The firms have no fundamental differences in both the technological selection (traditional sock-producing technology) and current technological levels. From a cognitive community perspective, firms in DSC are in the proximate cognitive community of technological knowledge. Three factors may explain this result. Firstly, the technologies and methods the firms adopted are comparatively traditional. Although the machines are imported from Italy or Japan, the operational principles are basically the same. Secondly, computerised sock knitting machines have gained prevalence in this area since year 2001, and most machines firms purchased were similar. Technological problems and solutions are also basically the same. A third and probably the most important factor is that the collective enterprises (or township-and-village enterprises, TVEs) established at the very early stage promoted the technological knowledge similarity between firms in DSC. Most entrepreneurs and technicians in DSC originated from several TVEs in the 1980s, and have acted as

1
2
3
4 technological knowledge disseminators, leading to a reasonably homogeneous
5
6
7 distribution of technological knowledge in DSC.
8

9
10 We failed to detect a positive relationship between the technological level and
11
12 firm size. For example, case JC is very small in size, but its technological level is
13
14 comparable to those of large enterprises. One deputy general manager of the large
15
16 firm WY gave the following comments on small firms specializing in outsourcing
17
18 during his interview:
19
20
21

22
23
24 *These producers are relatively strong in technology. Sometimes we even consult*
25
26 *them when we have problems in our internal production. After all, they have been*
27
28 *producing socks for ten to twenty years, and are very experienced. They are good at*
29
30 *technology, but there exists a very large gap between them and us in other aspects,*
31
32 *particularly in management and operational thoughts, and it's hard for them to*
33
34 *develop. At present, nearly 30% of the firms in Datang are our suppliers, and some*
35
36 *have been doing this for eight or ten years.* -WY D. GM
37
38
39
40
41
42

43
44 Different from their high congruence on technological knowledge structures,
45
46 firms in DSC have great diversity in business knowledge, especially between
47
48 large/medium-sized enterprises and small manufacturers⁷. In other words, from the
49
50 perspective of business knowledge structure, there are several sub-cognitive
51
52 communities at different development stages in DSC. Large/medium-sized enterprises
53
54 are at higher stages than small manufacturers in production management knowledge.
55
56
57
58
59
60 In terms of operational knowledge in international marketing, the difference is even

1
2
3
4 greater. Small manufacturers have so little knowledge about international marketing
5
6
7 that they know little about and never bother to know about the international market. In
8
9
10 terms of brand management knowledge, medium-sized enterprises are significantly
11
12 different from large ones.
13

14
15 The export ratio of large/medium-sized enterprises in DSC is about 70%, and
16
17 these firms normally take international marketing seriously and pay close attention to
18
19 the accumulation of international marketing knowledge. They are conscious about the
20
21 development trends of the industry. The deputy general manager of BP pointed out the
22
23 following during the interview:
24
25

26
27
28 *We must be concerned about international trade policy, e.g. antidumping and*
29
30 *quota, because they have great impact on our operation and production. The year*
31
32 *before last, the US government imposed quota limits on Chinese socks, which brought*
33
34 *great pressure on us. We did all the following to tide over the crisis: quickening the*
35
36 *pace to develop other external markets such as Japan, Korea and Europe, increasing*
37
38 *added value of products to raise profit margins, establishing overseas entities to avoid*
39
40 *tariff barriers, improving the competitiveness of the firm, and obtaining accreditation*
41
42 *of product quality (ISO9000 and ISO14000) and environmental protection (green*
43
44 *textiles).*
45
46

52
53
54
55
56
57
58
59
60
-BP D. GM

Two small-sized firms, JA and JB, are typically representative of small
manufacturers in DSC. These producers usually had fewer than 20 employees, and
specialised in supplying large or medium-sized firms. They had neither proper
management systems nor marketing staff and the entrepreneurs did all the managerial

1
2
3
4 work. Their communication circles were largely restricted in DSC. Though good at
5
6 sock-producing technology, these firms were not so at management and marketing.
7
8

9
10 The boss of a small-sized firm talked about the influence of industrial development on
11
12 his business:
13

14
15 *We usually don't care about where these products are exported. We just take*
16
17 *orders from and make socks for large-sized firms. Sometimes they turn to us for*
18
19 *technological advice, and they are inferior to us in technology. However, we don't do*
20
21 *such things as customs declaration, inspection, document attachment or management.*
22
23

24
25 *We just employ several people to produce socks.*
26
27

28
29
30
31
32
33
34
35
36
37

49
50
51
52
53
54
55
56
57
58
59
60
–JB Boss

32
33 As mentioned earlier, there are huge gaps in business knowledge structures
34
35 between the large and medium-sized enterprises, especially in brand management.
36
37 The large and medium-sized sample firms are engaged in both domestic and export
38
39 sales, but only three firms have their own brands, and two of the brands are influential
40
41 on the domestic market. In most circumstances, AL uses its own brand for export
42
43 sales. Other medium-sized firms mainly do outsourcing for other brands and know
44
45 little about brand management and operating modes.
46
47
48
49

50
51 To sum up, the two dimensions of knowledge distribution of DSC diverge. In
52
53 terms of technological knowledge, a high degree of homogeneity can be found and
54
55 there is no significant difference in the level of technological knowledge between
56
57 firms of different size. In contrast, when it comes to business knowledge, a high
58
59 degree of heterogeneity can be identified and a firm's level and type of business
60

1
2
3
4 knowledge are significantly related to its size. On the basis of the information
5
6
7 collected from interviews, we reckon that the similarity of technological knowledge
8
9
10 and heterogeneity of knowledge between firms in DSC may result from some unique
11
12 characteristics of TVEs.
13

14
15 TVEs were distinct products of China's transitional economy. It is very different
16
17 from the western system under which the individual is the ultimate owner of property
18
19 (BOWLES and DONG, 1999). It is a unique form of enterprise organisation based on
20
21 collective ownership and its property rights are in practice exercised by Town and
22
23 Village Governments (TVGs) (NAUGHTON, 1994). TVGs who own and control
24
25 TVEs have an objective defined more broadly than narrow economic interests and
26
27 profits. It may include social as well as ideological interests. In particular, it usually
28
29 includes employment maximisation. TVGs place a strong priority on employment
30
31 generation. Accordingly, most employees in TVEs come from local towns or villages
32
33 (BOWLES and DONG, 1999). In the context of DSC, small manufacturers appeared
34
35 in the mid-1980s and entrepreneurs of large enterprises emerged in the 1990s. Almost
36
37 all of them have had work experiences in TVEs and many entrepreneurs started their
38
39 business through privatization of the bankrupt TVEs. In the 1970s and early 1980s,
40
41 China was still a relatively isolated planned economy and TVEs focused their efforts
42
43 mainly on manufacturing and local trading rather than modern business activity such
44
45 as brand management, marketing planning and international trading. TVEs were more
46
47 willing to transfer knowledge and provide skill training than private owned or state
48
49 owned enterprises, making it easy for local employees to acquire technological
50
51
52
53
54
55
56
57
58
59
60

1
2
3
4 knowledge from them. However, as TVEs themselves were not good at modern
5
6
7 business management, they were unable to diffuse business knowledge effectively in
8
9
10 the region.

11
12 This historical factor has led to high heterogeneity of business knowledge and
13
14 high similarity of technological knowledge in DSC. At present, most sock firms in
15
16
17 DSC are small manufacturers who focus mainly on manufacturing semi-finished
18
19
20 socks. Only a few firms have learnt new business knowledge outside the cluster since
21
22
23 the privatisation of TVEs, and have the ability to incorporate small firms into their
24
25
26 subcontracting networks in DSC. Consequently, those with good business knowledge
27
28
29 have developed faster than others and grown into large enterprises.

30 31 3.2.2 Knowledge Diffusion Patterns in DSC

32
33 As described before, firms in DSC participated in different cognitive
34
35
36 communities according to their knowledge structures. The case study indicates that a
37
38
39 cognitive community's blocking and filtering effects have an important impact on
40
41
42 knowledge diffusion between firms in DSC.

43
44 In DSC, all firms selected almost the same technology, reached similar
45
46
47 technological levels, and were highly congruent in the technological knowledge
48
49
50 structure. In fact, they were in the same technological cognitive community. During
51
52
53 the interviews, we found that the firms frequently communicated with each other on
54
55
56 technological affairs, and this is similar to Marshall's "industrial atmosphere". Fig. 4
57
58
59 shows that localised technological knowledge is transmitted with extraordinarily high
60
efficiency and speed because the firms have a similar technological knowledge

1
2
3
4 structure.
5
6
7

8
9 ***Fig. 4 Main Channels for Acquiring Technological Knowledge⁸***

10
11 **<Fig 4 about here>**
12
13

14
15
16 It is noted that technological knowledge diffusion was not intentional by the
17 firms. In fact, the firms took various measures to keep their knowledge a secret, but
18 spontaneous knowledge spillover was unpreventable because the firms had similar
19 technological knowledge structures. The deputy general manager of WY and the chief
20 engineer of AL said:
21
22
23
24
25
26
27
28

29 *We usually sign agreements on secret information with subcontractors ... but the*
30 *effects are limited, and there'll be a lot of similar socks in Datang in several months...*
31
32 *We have no choice but to accelerate the pace of releasing new products!*
33
34
35
36

37 -WY V.CEO
38

39
40 *Generally speaking, because we have been making socks for so many years, we*
41 *could tell how to produce new products or new styles on the market simply by*
42 *glancing or touching them.*
43
44
45
46
47

48 -AL CTO
49

50 We also notice that the frequent interaction between the small manufacturers and
51 large enterprises involved only technological knowledge, rather than knowledge in
52 international trade and brand management. On the contrary, while there are no close
53 business relations, the medium-sized enterprises claimed that they obtained much
54 important information from the large enterprises in the cluster.
55

14
15 *They taught us useful knowledge about production and workshop management,*
16
17 *and we love to learn. But we do not know how to learn international trade. We just fill*
18
19 *the order, that's OK.* -JC BOSS
20
21

22
23 In fact, these phenomena reflected the blocking effect of a cognitive community
24
25 on knowledge flows. Even though geographical and relational proximity exist
26
27 between small and large manufacturers, and even though they have long term
28
29 cooperation, it is very hard for the small manufacturers to learn (international trade
30
31 knowledge) because they are not in the same cognitive community of business
32
33 knowledge. The medium-size enterprises have no close business links with the large
34
35 ones, but they are in the same cognitive community, and could be enlightened upon
36
37 some phenomena seeming irrelevant. As indicated in Fig 5, the most important
38
39 channel for firms in DSC to gain business knowledge is self-study.
40
41
42
43
44
45
46
47
48

49 ***Fig.5 Main Channels for Acquiring Business Knowledge⁹***

50
51 <Fig 5 about here>
52

53
54
55 The knowledge distribution between firms in DSC was homogeneous in
56
57 technology and heterogeneous in business knowledge. Technological knowledge
58
59 diffused under the control of a cognitive community's filtering effect, i.e.
60

1
2
3
4 technological learning mainly centered in DSC. On the other hand, a cognitive
5
6
7 community's blocking effect is evident in business knowledge diffusion, i.e. firms in
8
9
10 different business schema communities are significantly different in their learning
11
12 efficiency. The results suggest that firms' knowledge structures have a significant
13
14
15 impact on knowledge diffusion in DSC, and the existence of the blocking and filtering
16
17
18 effects in cognitive communities directly shape the mechanisms and efficiency of
19
20
21 knowledge diffusion.

22
23 In addition, our findings suggest that the complementarity between business
24
25
26 knowledge heterogeneity and technological knowledge congruence is an important
27
28
29 factor that has led to competitive advantage of DSC. A powerful flexible production
30
31
32 system has been developed in DSC because of high homogeneity in technological
33
34
35 knowledge, and large enterprises have been brought up with business knowledge
36
37
38 heterogeneity.

39
40 In fact, large enterprises play the role of leadership in DSC. They hold relatively
41
42
43 abundant managerial knowledge, have a better understanding of foreign buyers' needs,
44
45
46 and are more experienced in production management and quality control. After
47
48
49 getting big orders from overseas, they divide and subcontract them to dozens of small
50
51
52 manufacturers. In this way, they realise a flexible production with low cost. From the
53
54
55 perspective of the cognitive community, this kind of production can be realised
56
57
58 because of the existence of high-level but low-heterogeneity sock producing
59
60
61 knowledge in DSC. Therefore, the case study not only further verifies the explanatory
62
63
64 power of the cognitive community-based analytic framework for intra-cluster

1
2
3
4 knowledge diffusion, but also leads us to an important discovery that the combination
5
6
7 of various dimensions of knowledge distribution may be a new approach to explain
8
9
10 the formation and development of a cluster. That is to say, it seems that a cluster's
11
12 competitiveness is derived from a flexible production system within it, but a more
13
14
15 fundamental factor is the combination of various dimensions of knowledge (e.g.
16
17
18 technological and business knowledge) among the firms within it.

25 26 4. SIMULATION STUDY

27
28 The case study provides a snapshot of intra-cluster knowledge diffusion in DSC.
29
30
31 Since firms in Datang reached a high level of similarity in technological knowledge,
32
33 they have achieved diffusion efficiency in technology by the filtering effect of a
34
35
36 cognitive community. In contrast, due to their high dissimilarity in business
37
38
39 knowledge, the diffusion efficiency is low by the filtering and blocking effects of a
40
41
42 cognitive community. Even between those firms who have similar technological
43
44
45 knowledge and have developed a long term partnership, the diffusion of business
46
47
48 knowledge is still very hard due to the existence of the cognitive community's
49
50
51 blocking effect. Consequently, our case study shows that a cluster's distribution of
52
53
54 knowledge through the filtering and blocking effects of a cognitive community does
55
56
57 determine the process of knowledge diffusion in the cluster. However the case study
58
59
60 only provides a static cross-sectional description of knowledge diffusion in the cluster.
There is a dynamic relationship between knowledge distribution and knowledge

1
2
3
4 diffusion as they affect each other. The case study does not tell us this dynamic
5
6
7 process. For example, it is uncertain what will happen to knowledge diffusion when
8
9
10 both the heterogeneity and level of knowledge distribution are taken into
11
12 consideration, and whether a higher level of knowledge distribution leads to more
13
14 effective knowledge diffusion. Moreover, although it verifies the cognitive
15
16 community-based analytic framework for intra-cluster knowledge diffusion, the case
17
18 study is concerned with a traditional industrial cluster in China only. It is very
19
20 difficult to control proximity factors, e.g. industry and regulation, and to conclude
21
22 whether the knowledge diffusion pattern in DSC is a special case only.
23
24
25
26
27

28 To compensate for the deficiencies of the case study, we use an agent-based
29
30 simulation to simulate the dynamics of knowledge diffusion in a cluster, aiming to
31
32 find out whether the blocking and filtering effects of a cognitive community take
33
34 place in the short or long term, and obtain a better understanding of the phenomenon
35
36 of knowledge diffusion in a cluster.
37
38
39
40

41 Agent-based simulation is now recognised as one of the most promising new
42
43 tools for regional study, allowing us “to understand better the relations between
44
45 micro-processes (the decisions and behaviors of economic actors) and the emergence
46
47 of stylised facts common across much of industry (relating to R&D and the geography
48
49 of firms) in the model output” (TAYLOR and MORONE, 2005). Recently GILBERT
50
51 et al. (2001), PAJARES et al. (2003), MORONE and TAYLOR (2004) and COWAN
52
53 and JONARD (2004) have all used the agent-based methodology to study innovation
54
55 dynamics in clusters.
56
57
58
59
60

4.1 A Cognitive Community-based Knowledge Diffusion Model

We assume a global environment G consisting of a grid of $W \times W$ cells and a population of N agents ($N < W \times W$), representing a cluster and firms in it respectively. The grid is wrapped (i.e. a torus) so that there are no edge effects. Each agent is initially assigned a random position in the grid. Not all the cells of the grid are occupied by agents, and those occupied are occupied by only one agent. To simulate knowledge diffusion in the cluster, every agent $i \in \{1, 2, \dots, N\}$ is endowed with two types of knowledge randomly: the initial level of technological knowledge $k_i^T \sim U[T_d, T_u]$ and the initial level of business knowledge $k_i^B \sim U[B_d, B_u]$.

Given these types of knowledge in the cluster, every agent i has two sets of acquaintances: $\Gamma_T(i, t)$ and $\Gamma_B(i, t)$, representing the agent's technological and business acquaintances at cycle t . Agent i 's initial technological acquaintances $\Gamma_T(i, 0)$ and business acquaintances $\Gamma_B(i, 0)$ are all other agents on its MOORE neighborhood: those cells adjacent in the eight directions (north, south, east, west, northeast, northwest, southeast and southwest) and within the agent's visible range¹⁰. In our model, we call the unit of time a 'cycle'. In each cycle, every agent is permitted to interact with two acquaintances randomly chosen: technological acquaintance $p \in \Gamma_T(i, t)$ and business acquaintance $q \in \Gamma_B(i, t)$. Why does the agent choose two acquaintances respectively? The answer is that, according to the blocking effect of cognitive community, knowledge transfer may be more effective between firms belonging to the same type of cognitive community.

After agent i 's interacting learning with the acquaintance p and q , it will randomly choose another two agents $k \in \Gamma_T(p, t), l \in \Gamma_B(q, t)$ from the acquaintance

1
2
3
4 set of the two acquaintances interacted with and add the two new acquaintances to
5
6 agent i 's sets of acquaintances $\Gamma_T(i, t+1), \Gamma_B(i, t+1)$ respectively. Consequently,
7
8
9
10 with the simulation process, agent i 's two sets of acquaintances will become larger
11
12 and larger.

13
14 We suppose that while the interaction between agents i and j takes place, only
15
16 the agent who launched the interaction will have gains from interactive learning.
17
18 Agent i 's gains from the interaction are calculated in the following steps (MORONE
19
20 and TAYLOR, 2004):
21
22
23
24

25 Firstly, we calculate the distance in two types of knowledge between
26
27 agents i and j :
28
29

$$30 \quad \delta_i^T = k_j^T - k_i^T, \quad \delta_i^B = k_j^B - k_i^B$$

31
32
33 Then we calculate the knowledge/distance ratio in technological and business
34
35 dimensions:
36
37

$$38 \quad \varphi_i^T = \frac{k_i^T}{\delta_i^T}, \quad \varphi_i^B = \frac{k_i^B}{\delta_i^B}$$

39
40
41 Finally, we calculate agent i 's knowledge gains in two dimensions:
42
43
44

$$45 \quad g_i^T = \max\{\min\{\varphi_i^T, \delta_i^T\}, 0\}, \quad g_i^B = \max\{\min\{\varphi_i^B, \delta_i^B\}, 0\}$$

46
47
48 The above knowledge gain function embodies the filtering effect of a cognitive
49
50 community: even for firms within the same type of cognitive community, knowledge
51
52 diffusion between them still does not occur easily if the difference between their
53
54 development stages of knowledge is too large. In Fig. 6, we depict agent i 's (where i
55
56 has different levels of knowledge: 1, 5, 10) knowledge gains that arise through
57
58 interaction with agent j . We can see two things: the higher the level of the agent, the
59
60

more it gains from interaction; and the smaller the difference between the two agents, the more the agent can gain.

To measure knowledge diffusion using a simulation, we provide two groups of indices: the average knowledge level $\mu^T(t)$, $\mu^B(t)$ and the standard variance of the knowledge level $\delta^T(t)$, $\delta^B(t)$. Using these indices and relevant figures, we can grasp some important information about knowledge distribution and diffusion in the simulation.

$$\mu^T(t) = \frac{1}{N} \sum_{i=1}^N k_i^T, \quad \mu^B(t) = \frac{1}{N} \sum_{i=1}^N k_i^B$$

$$\delta^T(t) = \sqrt{\frac{1}{N} \sum_{i=1}^N (k_i^T - \mu^T(t))^2}, \quad \delta^B(t) = \sqrt{\frac{1}{N} \sum_{i=1}^N (k_i^B - \mu^B(t))^2}$$

Fig. 6. The Knowledge Gain of Agent i with an Initial Level of Knowledge Equal to 1, 5 and 10

<Fig 6 about here>

4.2 Setting and Results of Simulation Experiment

4.2.1 Setting of Simulation Experiment

We performed the simulation with a population of 300 agents allocated randomly over a wrapped grid of dimensions 21×21 units (i.e. a total of 401 cells) (see Fig. 7). To explore the relationship between knowledge distribution and diffusion, the agent's initial interval of knowledge distribution is classified into three types: $[0,150][0,50][50,100]$, indicating high level and high heterogeneity of knowledge distribution (HH), low level and low heterogeneity of knowledge distribution (LL), and high level and low heterogeneity of knowledge distribution

1
2
3
4 (HL)¹¹ respectively. Since there are two dimensions of knowledge, technological and
5
6
7 business, combining the three types of knowledge distribution in each dimension, we
8
9
10 will have nine (3×3) classes of cluster. As set in the simulation model, there is no
11
12 difference in the agent's learning strategy in technological and business knowledge
13
14 dimensions, and the diffusion of these two types of knowledge is operated
15
16 independently by a cognitive community's blocking effect. To save space, in the next
17
18 two sub-sections we mainly focus on the dynamics of technological knowledge
19
20 distribution and diffusion, and the dynamics of business can be inferred from it¹².
21
22
23
24
25
26
27

28 ***Fig. 7. 300 Agents on the Wrapped Grids***

29
30 **<Fig 7 about here>**
31
32
33
34

35 In the following part, we report the result of three clusters: high level and high
36
37 heterogeneity of technological knowledge (HH), low level and low heterogeneity of
38
39 technological knowledge (LL), and high level and low heterogeneity of technological
40
41 knowledge (HL). Meanwhile, we let agents interact 30 cycles and 300 cycles to
42
43 observe dynamics in both the short and long term.
44
45
46
47
48
49

50 **4.2.2 Results of Long Term Analysis**

51
52 After letting agents interact for a period of 300 cycles, we observed that
53
54 irrespective of the initial distribution of technological knowledge, all three types of
55
56 cluster almost converged¹³. The only difference between them is the velocity of
57
58 convergence. The HL cluster converged first, followed by the LL cluster, and finally
59
60

1
2
3
4 the HH cluster.

22
23 <Figs 8-10 about here>
24

25
26
27 Industrial technology progresses fast in a knowledge economy. The only way for
28 firms to maintain competitiveness is to keep learning new knowledge of technology
29 and business. Knowledge in a cluster converges in the long term so that it is very
30 important for firms to acquire new knowledge rapidly and efficiently in the short term.
31
32 We now analyse the short term dynamics of knowledge distribution and diffusion.
33
34
35
36
37
38
39

40 **4.2.3 Results of Short Term Analysis**

41
42 Knowledge diffusion dynamics in a cluster is comparable to macroeconomic
43 evolution, and the short-term dynamics of knowledge diffusion may be more
44 important for firms. Our results of the short term simulation show that in the HH, HL
45 and LL clusters, the initial distribution of technological knowledge plays an important
46
47
48
49

Fig. 12. The Short Term Dynamics of HL Cluster

<Figs 11-12 about here>

In the HL cluster, the agents' technological knowledge quickly achieved convergence with a high mean and low standard variance. This may indicate that knowledge is diffused effectively between the agents by the filtering effect of a cognitive community when they all belong to a highly developed sub-cognitive community of the same type. Such high efficiency of knowledge diffusion is also evident in the graph of the agents' knowledge distribution at different stages. As the agents in the HL cluster have a comparatively high level of technological knowledge, after 20 cycles of simulation, almost all agents have achieved the level of knowledge 100, and all agents in the cluster have reached the level of knowledge 50 by cycle 30.

Fig. 13. The Dynamics of Agents' Distribution of Knowledge in the HL Cluster

<Fig 13 about here>

The filtering effect of a cognitive community is also evident in the LL cluster. Although the agents in the LL cluster have improved their technological knowledge through 30 cycles of interaction, the standard variance of the agents' technological knowledge has not declined, indicating that some agents have absorbed the knowledge very quickly but others have done it slowly. As the agents in the LL cluster have a relatively low level of technological knowledge, knowledge exchange among them is more difficult due to the filtering effect of the cognitive community. Some

1
2
3
4 agents with a relatively high level of technological knowledge benefit a lot from the
5
6 interaction, but other agents with a relatively low level of knowledge only benefit a
7
8 little. From the graphs of the agents' knowledge distribution at different stages it can
9
10 be seen that, after 20 cycles of simulation only half of the agents arrived at the level of
11
12 knowledge 50, and even by cycle 30, some agents still had not reached the level of
13
14 knowledge 50.

28 **<Figs 14 and 15 about here>**
29
30
31

32 The most interesting discovery of the short term simulation is the result of the HH
33
34 cluster. From fig. 11, we can see that although HH has a relatively high level of
35
36 average knowledge, its heterogeneous knowledge distribution leads to an
37
38 extraordinarily low diffusion efficiency. This phenomenon is very interesting, because
39
40 we usually expect that a high level of average knowledge distribution ensures active
41
42 knowledge diffusion in a region. In reality, some regions replicate the development
43
44 modes of other successful regions, and during the process, they focus particularly on
45
46 the development of local research institutes to improve the average level of local
47
48 knowledge distribution. However, this strategy does not often lead to an ideal result.
49
50 The simulation in the HH cluster indicates that, although a high level of average
51
52 knowledge distribution is of vital importance, distribution heterogeneity also plays a
53
54 key role. To realise highly efficient knowledge diffusion in a cluster, we must ensure a
55
56
57
58
59
60

1
2
3
4 high level and low heterogeneity of knowledge distribution among agents in the
5
6
7 cluster.

8
9 The HL cluster represents a cognitive community with highly developed
10 technological knowledge, and the LL cluster a less developed one, but the HH cluster
11 represents one with significant differences inside. The simulation experiment on the
12 three clusters shows that the filtering effect of a cognitive community is evident.
13
14 Technological knowledge is diffused more effectively in HL than the other clusters.
15
16
17 Firms in the HL cluster can learn more and at a higher speed.
18
19
20
21
22
23

24
25 In sum, the simulation of knowledge distribution and diffusion leads to two
26 findings:
27

28
29 (1) In the long term, a cluster's initial distribution of knowledge has no
30 significant effect on knowledge diffusion within the cluster. Irrespective of the initial
31 distribution of knowledge, all agents in the three clusters can converge to the similar
32 level of knowledge.
33
34
35
36
37
38
39

40
41 (2) In the short term, a cluster's initial distribution of knowledge has a critical
42 effect on the process of knowledge diffusion. The HL cluster can stimulate knowledge
43 diffusion among agents within it, enabling the agents to converge to a high level of
44 technological knowledge more quickly than the LL cluster and HH cluster. Since the
45 agents have a low initial level of technological knowledge, interactive learning
46 between agents in the LL cluster is less effective. Most interestingly, although the HH
47 cluster has a high level of average knowledge, the differences between the agents are
48 too dramatic, and the knowledge diffusion efficiency of the HH cluster is even lower
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3
4 than that of LL cluster under the influence of the filtering effect of the cognitive
5
6
7 community.

8
9 Compared to the static results of the case study in section 3, our agent-based
10
11 simulation reveals some interesting findings. As all agents in a cluster can keep
12
13 learning for a long time to achieve a similar level of knowledge, the heterogeneity of
14
15 technological knowledge in the cluster may be a short term phenomenon. However,
16
17 the speed of the convergence process depends on the cluster's initial distribution of
18
19 knowledge. A cluster with a high level but low heterogeneity of initial knowledge has
20
21 an advantage in the speed of knowledge learning and diffusion. As shown in the short
22
23 term simulation of clusters HL, LL and HH, both heterogeneity and the level of
24
25 knowledge distribution play an important role in knowledge diffusion.

37

38 5. CONCLUSIONS

39 This paper has adopted a perspective of firm knowledge structure in a cluster to
40
41 discuss the issue of intra-cluster knowledge diffusion. A cognitive community-based
42
43 analytic framework is established, a case study on a cluster from China is conducted
44
45 and an agent-based simulation is performed to further verify it. Several conclusions
46
47 can be drawn from the case study and simulation:
48
49
50

51
52 1. Our cognitive community-based framework provides some new thoughts and
53
54 insights into the phenomenon of intra-cluster knowledge diffusion. Given the
55
56 cognitive community's blocking and filtering effects, it is important to establish a
57
58 high level and low heterogeneity of knowledge distribution in a cluster with which it
59
60

1
2
3
4 will be relatively easy for knowledge to diffuse at a high speed. Our simulation study
5
6
7 proves that knowledge diffusion in a cluster with a high knowledge level but low
8
9
10 knowledge heterogeneity is most efficient, followed by the one with a low knowledge
11
12 level and low knowledge heterogeneity, and finally by one with high knowledge level
13
14 and high knowledge heterogeneity.

15
16
17 2. A cluster's knowledge distribution may not be as homogenous as the traditional
18
19 wisdom would suggest. However, it may not be purely heterogeneous either. Our case
20
21 study shows that knowledge distribution in DSC is relatively homogenous for
22
23 technological knowledge but heterogeneous for business knowledge, which renders
24
25 the cluster different diffusion efficiency in different dimensions of knowledge and
26
27 gives DSC potential for success. Given the homogeneous distribution of technological
28
29 knowledge, firms in DSC belong to the same cognitive community at a high
30
31 development stage, leading to fluent and efficient local learning and diffusion of
32
33 technological knowledge. This pattern of technological knowledge diffusion is very
34
35 much like the "industrial atmosphere" described by Marshall. In contrast, as DSC has
36
37 a heterogeneous distribution of business knowledge, the diffusion of such knowledge
38
39 is rare. Even for firms maintaining technological cooperation for many years, there is
40
41 little business knowledge diffusion. Apart from several large firms acquiring business
42
43 knowledge from outside DSC, most small and medium-sized firms learn business
44
45 knowledge by self study. While existent studies either presume knowledge
46
47 homogeneity or merely consider technological knowledge and neglect the business
48
49 dimension, our investigation considers multi-facet knowledge distribution and hence
50
51
52
53
54
55
56
57
58
59
60

1
2
3
4 provides new insight into the phenomenon of intra-cluster knowledge diffusion.
5
6

7 3. In a cluster, some firms may hold the position of “gatekeepers” by their knowledge
8
9 endowments, and they may determine the characteristics and development direction
10
11 of the cluster. In DSC, the leader firms behave differently in the technological and
12
13 business cognitive communities. In the technological cognitive community, they have
14
15 to act as “generous gatekeepers” to communicate with others either consciously or
16
17 unconsciously, because firms in DSC have highly homogeneous technological
18
19 knowledge, and because it is very difficult to keep technological knowledge secret
20
21 due to the filtering effect of a cognitive community. However, the leader firms in DSC
22
23 behave more like “stingy gatekeepers” in diffusing business knowledge. These leader
24
25 firms may exploit business knowledge exclusively by the cognitive community’s
26
27 blocking and filtering effect, as firms are highly heterogeneous in business
28
29 knowledge,
30
31
32
33
34
35
36
37

38 4. Both the case study and simulation indicate that a high knowledge level but low
39
40 knowledge heterogeneity in a cluster can have a very important impact on its
41
42 competitiveness. However, due to the lack of a public knowledge infrastructure basis,
43
44 such as resources in science and technology education and social service
45
46 organisations, it is hard for most developing countries to obtain the important initial
47
48 distribution of high-level knowledge with low-knowledge heterogeneity in order to
49
50 realise large-scale diffusion of knowledge and skills in the short term. Nevertheless,
51
52 we have found that collective enterprises or town-and-village enterprises, a product of
53
54
55
56
57
58
59
60 China’s transitional economy, laid an important foundation for the formation of

1
2
3
4 high-level knowledge and low-knowledge heterogeneity in DSC in the 1980s.
5
6
7 Although most collective enterprises or town-and-village enterprises went bankrupt or
8
9 were privatised in the 1990s, the initial knowledge distribution they formed was an
10
11 important premise for the development of DSC. It shows that for clusters in
12
13 developing countries, even developed ones, an appropriate knowledge distribution is
14
15 the prerequisite condition for their formation and development. From the experiences
16
17 of China's clusters such as DSC, TVEs as a product of transitional economy
18
19 contributed much to building such knowledge distribution. Even though other
20
21 countries may not have such historical opportunities, there are many equivalents such
22
23 as universities or trade unions which can have similar effects.
24
25
26
27
28
29

30
31 5. Last but not the least, our research provides a new explanation for sources of a
32
33 cluster's competitiveness. Our case study shows that the combination of various
34
35 dimensions of knowledge distribution may be fundamental for the formation and
36
37 development of a cluster. That is to say, it seems that although a cluster's
38
39 competitiveness is derived from the flexible production system in it, a more
40
41 fundamental factor is the combination of various dimensions of knowledge (e.g.
42
43 technological and business knowledge) among the firms in it. In DSC, there is a
44
45 high-level homogeneity distribution of sock producing knowledge and high
46
47 heterogeneity distribution of business knowledge, which gives large enterprises an
48
49 opportunity to utilise the local capacity of low cost flexible production. By their
50
51 relatively abundant managerial knowledge, better understanding of foreign buyers'
52
53 needs, and greater experience in production management and quality control, large
54
55
56
57
58
59
60

1
2
3
4 enterprises often get big orders from overseas. As there are numerous small
5
6
7 manufacturers with high sock producing technology, large enterprises divide and
8
9
10 subcontract foreign orders to these partners conveniently. In this way, they realise
11
12 flexible production with low cost and gain tremendous advantage over their
13
14
15 competitors located outside DSC.

16
17 The study is an exploratory one using a perspective of the cognitive community to
18
19
20 interpret the phenomenon of intra-cluster knowledge diffusion. Several limitations
21
22
23 need to be noticed and overcome in future.

24
25 (1) Our analytic framework is focused on intra-, rather than extra-cluster knowledge
26
27
28 diffusion, and the knowledge transferred from outside is not discussed in detail.

29
30 Knowledge diffusion from outside may be very important for a cluster's development
31
32
33 and innovation. As BELL and ALBU(1999) point out, for developing countries, the
34
35
36 need for technological chasing and developing means that extra-cluster knowledge
37
38
39 diffusion may have a great impact on cluster development. In future, a study
40
41
42 incorporating outside knowledge diffusion into the analysis would enable us to know
43
44
45 more about the topic.

46
47 (2) Our cognition-based analytic framework argues that only those firms with similar
48
49
50 knowledge structures would be efficient in learning and transferring knowledge. This
51
52
53 framework is in nature a knowledge diffusion model, implying that a small
54
55
56 knowledge gap between firms facilitates knowledge learning and diffusion. Although
57
58
59 the diffusion of similar knowledge enhances firms' technological capabilities and
60
places them in a better position for innovation, our paper has not provided an explicit

1
2
3
4 discussion of the relationship between knowledge diffusion and innovation while
5
6
7 advancement in a cluster demands further knowledge that allows modernisation,
8
9
10 innovation and adjustment. Consequently, in future research more attention should be
11
12 paid to the relationship between innovation and diffusion.
13

14
15 (3) In addition to firm knowledge structures, other micro-level variables such as
16
17 strategy orientation, organisational structure and entrepreneurship need to be
18
19
20 considered in future studies of cluster knowledge diffusion.
21

22
23 (4) Although DSC is representative of China's traditional clusters, our case study
24
25 covers 8 firms only, which may limit the interpretation of the findings from this study.
26
27
28 A larger sample size would be preferable in future research.
29

30
31 (5) In order to simplify the simulation model, we do not distinguish between large and
32
33 small enterprises and we assume that all firms have complete information about each
34
35
36 other's knowledge, which may restrict the model's explanatory power.
37

Table 1. Summary of the Major Characteristics of the Firms⁴

Firm	Duration in years	Size	Product	With/without brand
WY	>10	Large	Finished socks	yes
AL	>10	Large	Finished socks	yes
BR	>10	large	Finished socks	yes
SWT	>10	medium	Finished socks	no
SBL	>3	medium	Finished socks	no
JA	>10	small	Semi-finished socks	no
JB	>3	small	Semi-finished socks	no
JC	>10	small	Semi-finished socks	no

Table 2. Examples of Data Coding⁵

Coding Category	Example
Types of technology	Our major business is sock-making, part of our production is outsourcing
Level of technology	Our technology is just on average, but we are making rapid progress through efforts.
Technological development strategy	There have been no vast changes in this industry, and the major problem at present is how to raise productivity.
Market orientation	Our major clients are from abroad. We accept foreign orders and subcontract them to other manufacturers
Market development ability	I think we are better at market development than others. Our knowledge about how to conduct foreign trade brings us competitive edge.
Business strategy	We feel that capital, technology and management are very important, and all these aspects must be strengthened for the firm's development.
Communication Channels for technology	We usually turn to local technicians to solve technological problems, but we do this informally. We seldom communicate technology outside Datang.
Communication channels for market	Whether we can get orders depends on our own.... I think knowledge gained from college education to be of great help, such as English and marketing.

NOTES

1. SHANE (2000) proposes that three dimensions of prior knowledge are important to the process of entrepreneurial opportunity discovery: prior knowledge of markets, of ways to service markets, and of consumer problems. TSAI (2001) and COHEN and LEVITHAL (1990) suggest that technological knowledge is an determinant of a firm's competitiveness. In addition, NOOTEBOOM et al (2007) define a firm's knowledge base as its technological knowledge. Furthermore, in the tradition of research in managerial and organizational cognition (WALSH, 1995), schema and knowledge structure are used interchangeably.
2. In Fig. 1, CC1 represents a cognitive community of type 1, so do CC2, CC3,....
3. We represent a cognitive community in the following way: the first letter denotes the category of knowledge, technological or business; the first and second numbers indicate the type and development stage of a schema respectively. The greater the second number the more developed a schema. For example, (B3-1) represents a less developed business schema of type 3.
4. According to the characteristics of the Chinese sock industry, we define firm size as: small, staff number \leq 100; medium, $100 <$ staff number \leq 300; large, staff number $>$ 300.
5. Because of space limitations, we list the classification of the first level categories only.
6. For the convenience of diagram drawing, we use different symbols to represent

different firm sizes. A star represents large size; a diamond represents medium size; and a triangle represents small size. In the diagram, the ordinate stands for knowledge type, and the abscissa for the development level of certain knowledge type.

7. As there is a significant relationship between the level of business knowledge and firm size, we reckon that business knowledge may be more important for a firm's competitiveness.
8. The assessment indexes are formed according to the relevant information about channels for obtaining technological knowledge in the coding part. All important channels mentioned by the interviewees are listed.
9. The assessment indexes are formed according to the relevant information about channels for obtaining business knowledge in the coding part. All important channels mentioned by the interviewees are listed.
10. In the model, we set an agent's visible range to 1.
11. Here, we set the probability distribution of the agent's knowledge as uniform distribution,

$$X \sim U(0,150), E(X) = 75, D(X) = 1875 \quad Y \sim U(0,50), E(Y) = 25, D(Y) = 208\frac{1}{3};$$

$$Z \sim U(50,100), E(Z) = 75, D(Z) = 208\frac{1}{3}$$

12. The detailed simulation results of other classes of cluster are not presented because of space limitation but available upon request.
13. This seems to confirm a common saying that "time permitting, we can do anything". So long as agents continue learning, they will eventually achieve their
